Sqt. Half-Mast. PS Magagine. Good Kasarks

A T53-L-13 gas turbine powers this baby. The 1400 shaft horsepower, flat rated to 1100, produces roughly 300 SHP more than the T53-L-11B engine. With a slim, trim design she wades into the fracus at up to 190 knots.

There're several "firsts" in this latest model in the Hucy-series. The big feature is the stability augmentation system (SAS) which provides a stable weapons delivery platform. The latest armor plating for critical parts of the bird is included.

Self-scaling fuel and oil tanks, plus duplicate hydraulic control systems, are just part of her rugged make-up. She can take it — as well as dish it out.

With only a 2-man crew — a co-pilot/gunner firing the TAT-102A and the pilot/gunner firing the wing guns and rockets (as well as the TAT-102A in the fixed position) — there's no flying crewchief.

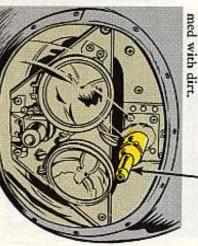

So-o-o-o, it's mighty important that pilots freely discuss deficiencies, during

Eyeball the area for skin cracks and dents.

MAKE SURE ...

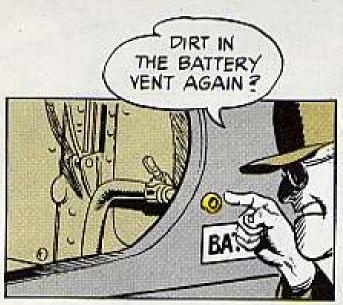

- The nose compartment is clean, with no corrosion around the battery, and the battery and landing light connections are tight; check the wing stores jettison and transmission oil level circuit breakers for proper setting.
- All the screws are in the landing light cover and there're no cracks or gaps in the transparent plastic around the pitot tube.

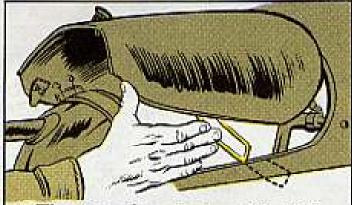

The pitot tube's not dented, or jammed with dirt.

 The nose door latches OK. When you close the door push in on the wire guides so they don't get broken off.

GLAD, I FOLLOWED

CONNIES ADVICE, AND

SMEARED SOME ZINC

CHROMATE PUTTY (MIL-P8116)

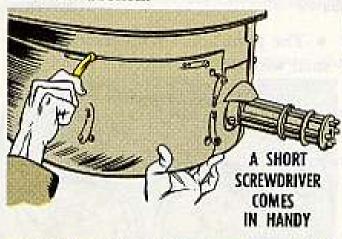

AROUND THE PITOT TUBE...

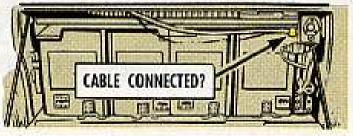

WE'D HAVE SHORTED OUT

LIGHTS BY NOW!

Focus on the turret to see that all the cowling fasteners are secure, and none are broken.

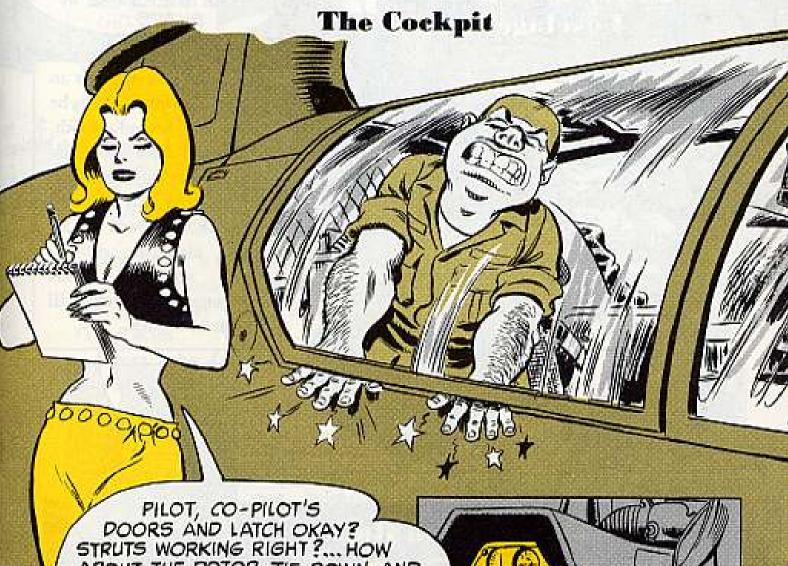

Be sure the turret ammunition doors latch properly. Eye the electrical receptacles in the ammunition bay for damage and corrosion.

Make sure the ammo chute and turret drive cable are not damaged and that they're connected.

Co-pilot tip—Make sure your TAT-102A is stowed and the sight elevation lock engaged when the bird comes in to roost.

The automatic gun will hit the ground in the straight-down position. There's a ground safety lever on the right side of the TAT-102A sighting station. Lever engagement restricts the turret from depressing more than 20 degrees.

Look for turret hydraulic leakage which will show up in the ammunition bay. See if the searchlight is damaged.

-with one exception.

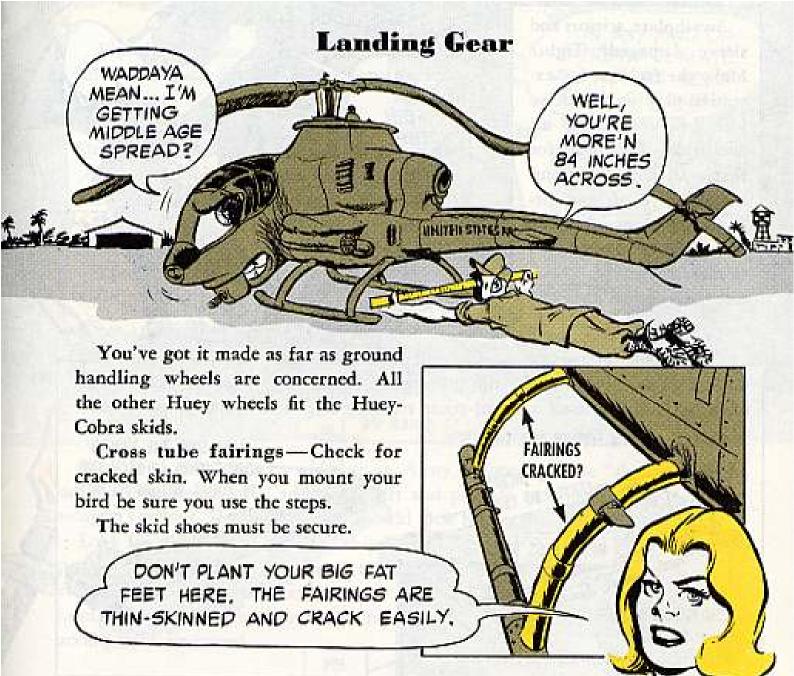

The pitch horns are altered to permit direct connection between the swashplate and the rotor . . . simplifies the control system. You'll find the repair limits in Chap 8 of TM 55-1520-221-20 (13 Nov 67).

Mount your charge and focus on the hub, blade grips, pitch horns, drag

braces and sand deflector. Look for visible cracks and check for tightness.

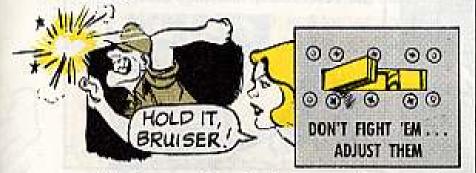

Any obvious scratches, nicks, dents, crosion of the leading edge or bond failures bear further looking into.

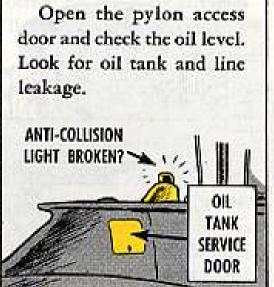

Pylon

Cowling, access doors and inspection plates have any broken fasteners or latches?

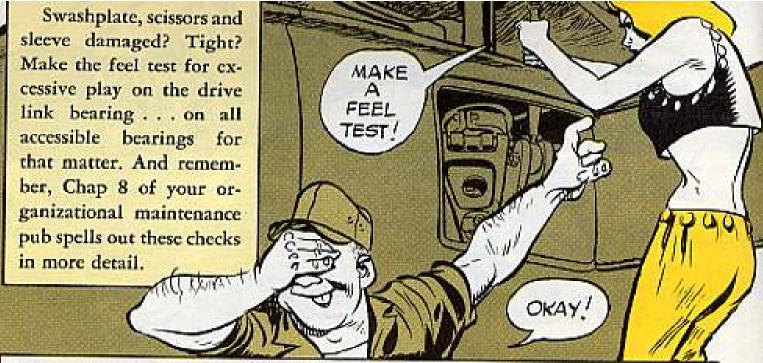

All the cowling latch receptacles can be adjusted to give you added clearance for the right fit . . . adjust 'em.

The exposed part of the mast should be clean. Look for possible damage.

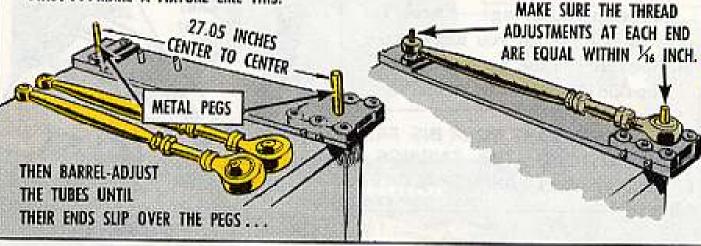

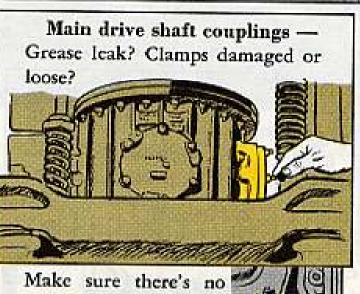

Here's how you can take the guess-work out of adjusting the pitch change tubes and save yourself a lot of rotor tracking after a main rotor replacement.

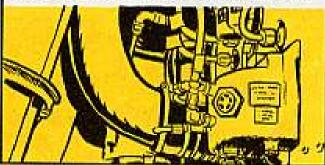

Make sure there's no water in the transmission sump and that the oil level is up-to-snuff.

Hydraulic compartment — damaged? Secure? No leaks around the reservoirs, modules and lines?

Fluid level in the reservoirs OK?

Deplete the collective accumulator for a check of the No. 1 system.

Something new has been added to an Army chopper—those "shorty" wings on the HueyCobra give additional lift and provide mounting points for the weapon's pylons. Here's what you should look for on the Daily.

Look for dents in the skin and chipped paint. Make sure the decals are readable and that the safety pins are installed so the external stores can't be accidentally jettisoned.

PIN Secure

Remember—clean the ejector rack at the end of each firing day in which the emergency jettison is used. Also, replace the orifice on the outboard ejector rack after each second jettison of stores. You'll find the cleaning poop in Chap 14 of your organizational maintenance pub.

Here's another tip. The electrical connection to XM-18 armament subsystem will pop out due to vibration (which means the weapon can't be fired) unless you take this action:

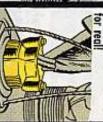

Unscrew this adapter, which is actually a lock, from the pylon.

Screw the adapter Then hook in your onto the XM-18 electrical plug which trical receptade con- locks into the adapter nection.

... holds that plug

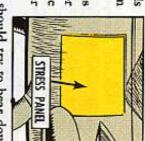

Remember, tho, when the pod is jettisoned for any reason, the adapter goes right along with it. So, it might pay you to have a couple of those locking adapters, PNN ODR-145, FSN 5935-062-4643 on hand.

This weapon will clear all ammunition from the 6 barrels after the trigger is released but you can't see that this operation has been accomplished for sure. So, never rotate that weapon because if there should be a round in the chamber it will fire.

Heeding the poop on decals can also keep your bird from taking it on the chin.

Take the aft fuel tank stress panel. You can take it off for inspections but just be sure you have some support under the tail boom.

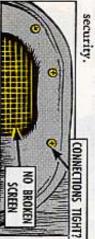

The support is only a precaution in case somebody should try to bear down on the tail boom to install ground handling wheels while the panel is off . . . would buckle some of the airframe structural members for real!!

External drains clogged? Remember that water, being heavier than JP-4, will settle to the bottom of the fuel tanks. So, every day, get rid of that water contamination in the tanks by draining it into a sampling jar. Drain the fuel filter on the left side of the engine daily (battery must be on). Fuel line or fuel cell leaks?

Next, check the oil cooler air inlet screen for broken wire. Give the oil cooler the once-over for security.

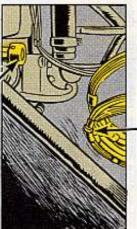

Unlarch the panel to the electrical compartment and give the wiring and components the onceover.

Tail rotor boost cylinder leaking? Cylinder support loose?

Hydraulic cylinders and lines leaking? Tight? Hydraulic accumulator precharged in the green? Tis mighty important that this standby emergency hydraulic system is ready to go if needed.

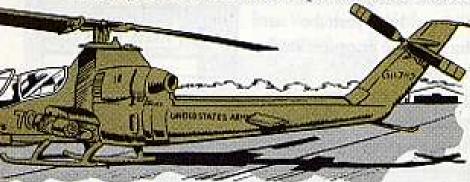

IN THE GREEN?

The increased horsepower T53-L-13 weighs about 40 pounds more than the T53-L-11B. One more gas producer turbine stage and one more

power turbine stage in the combustor section accounts for most of the weight.

With the added stages the turbine inlet temperature is reduced and since the turbine blades are more lightly loaded, you get more reliability. You'll probably get longer life on hot section components due to the lower temperatures.

Upper fairing and cowling—Holes or cracks? If you see a hairline scratch

. . . make the sound test!

TAP AROUND THE AREA.

IF YOU GET A DIFFERENT

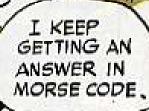

SOUND IN ANY ONE SPOT... YOU

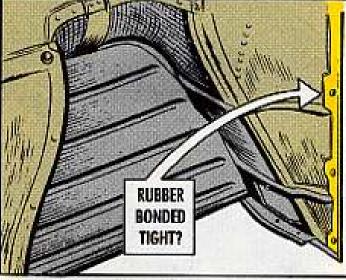

PROBABLY GOT A CRACK.

Tailpipe fairing—Hose or cracks? Go over the rubber insulation on the fairing to make doubly sure it's securely bonded. Here's why.

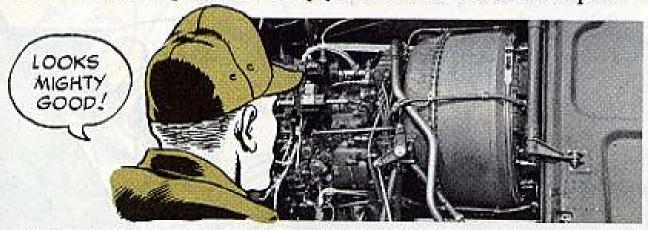

There's a transmission and engine oil-cooling blower mounted on the second section of the tail rotor drive shaft. This baby has no controls or clutches and draws cooling air thru a screened duct in the left side of your HueyCobra.

This blower runs all the time the engine is running. The only problem is that any hunk of rubber or a loose rivet in the doghouse can be sucked into the fan. You know what happens when it hits the fan — the blower coupling on the shaft is sheared in seconds and your bird is grounded for a blower change.

Look over the blower for damage and a possible grease seal leak and, above all, make doubly sure the doghouse is clean as a whistle. A rise in engine oil or transmission oil temperature will tip you off that the blower is kaput.

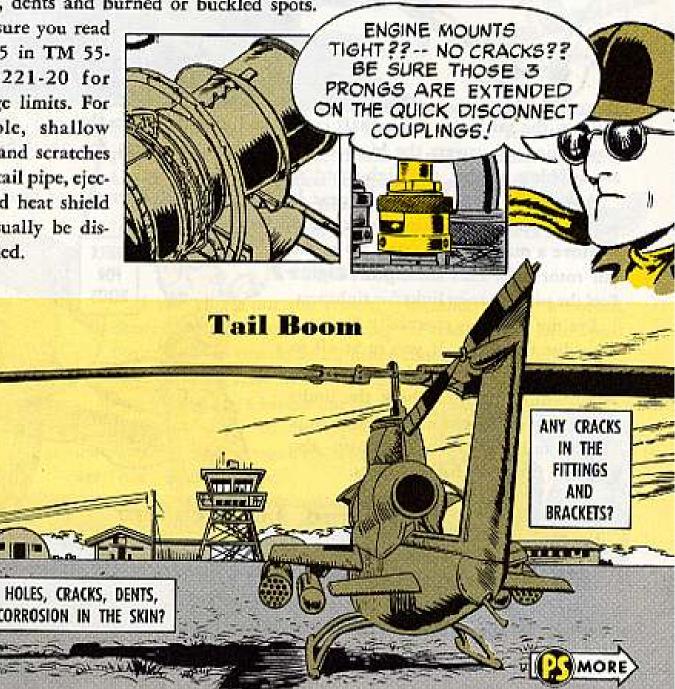

Engine accessories and connections secure? Not damaged?

Control linkages actuator and cambox secure?

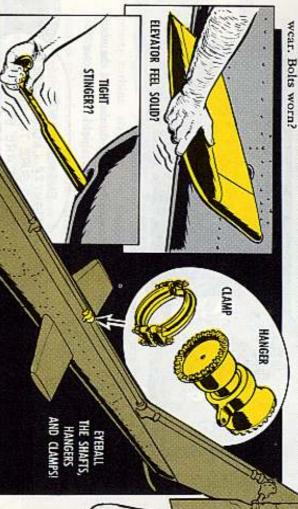

Run your eyeballs over the engine compressor housing, combustion chamber housing, exhaust diffuser, support cone, tailpipe heat shield and ejector for cracks, dents and burned or buckled spots.

Be sure you read Chap 5 in TM 55-1520-221-20 for damage limits. For example, shallow dents and scratches in the tail pipe, ejector and heat shield can usually be disregarded.

Plant your mitts on the elevators and tail skid to see if you've got that "solid"

Putting it back: Be sure you just screw the cover in hand-tight — don't use a tool. And, remember, you don't need an O-ring here.

TIP: Use a rag to catch the hydraulic fluid that comes out when you remove the filter element — and mop up good after you're through. Else the oil will catch dust and you'll catch trouble.

PLAY REAL SAFE WITH MINNIE

Minnie in a turret is no Juliet on a balcony. She's likely to be even more of a spitfire than the Minnie in an M21 subsystem or in an XM18 pod . . . one reason being that you can't get inside the turret to pull out the safing sector.

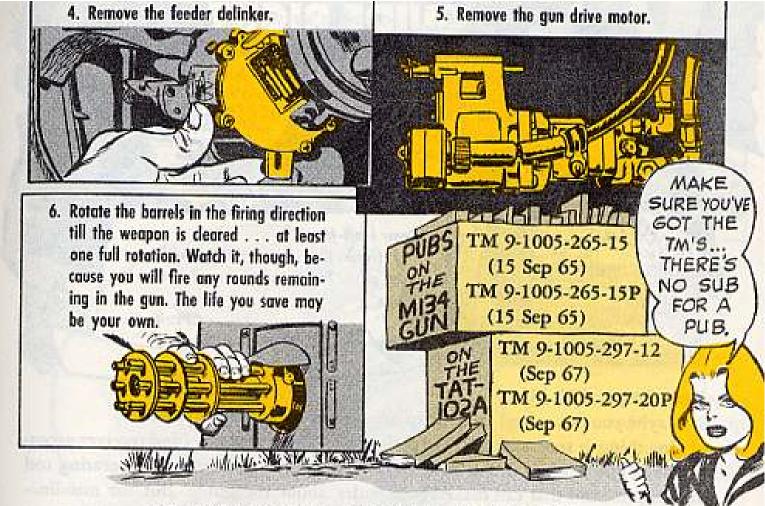

But, here's an alternate method that will go a long way toward keeping Minnie from biting you:

1. Clear the down range area. And you stand clear of the

2. Turn the barrels opposite to firing direction till you meet resistance.

MACHINE GUN GUIDE

If you are a machine gunner by trade, paste this in your helmet. It gives you the link type and direction of feed for every kind of machine gun.

^{*}Built to feed from one direction. Cannot be reversed.

^{**}Could be set to feed this way but never is.

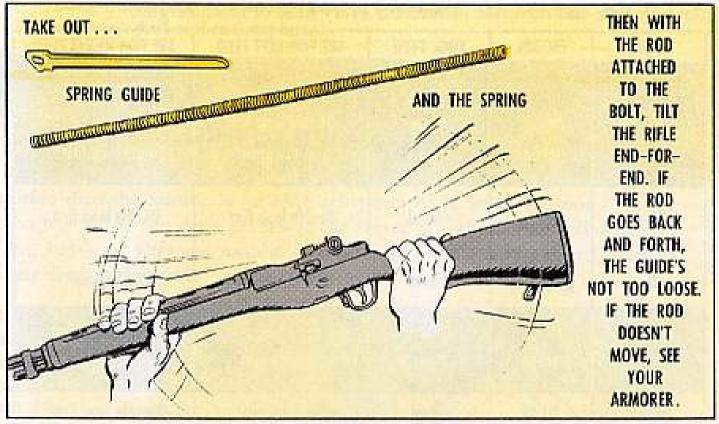

Dear Corporal Y. M.,

Maybe you do . . . and then again maybe you don't have trouble.

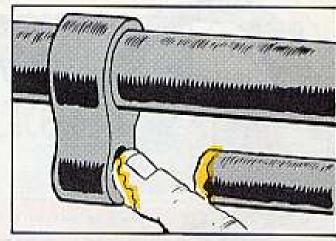

One thing is sure with an M14 scries rifle. When the barrel and receiver group is out of the stock you can have some misalinement between the operating rod and piston. And that can make you wonder about the guide. But the misalinement all but disappears when you put the whole works back together.

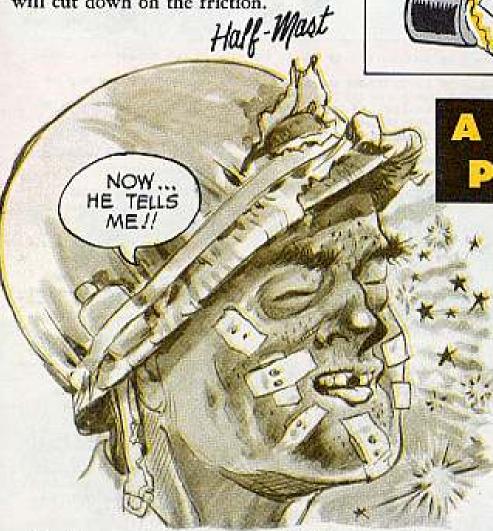

TRY THIS QUICK TEST

One reason the guide loosens . . . the way some guys make with the muscles as they pull and twist the operating rod out of the guide in disassembling the rifle.

Something else . . . there's metal-tometal contact between the rod and piston — plain and simple. A little rifle grease or PL Special (LAW below 0°F) on the inside of the guide and the part of the rod that goes through the guide will cut down on the friction.

It can happen
... and has — the tip
of the firing pin for the
M14 rifle breaks
and gets hung up
in its hole in the bolt.
The tip sticks out
of the hole a bit
and hits the primer
as the cartridge
is being chambered.

You know what happens next. Right—the cartridge fires and because it's not fully seated in the chamber, it rips open at the primer end. Chalk up a

BUSTED FIRING PIN?

busted weapon and maybe a you, too.

So it's a wise guy who checks the tip of the firing pin every time he cleans his shooter. And he should get rid of any pin that has a cracked or chipped tip, no matter if the pin is old or new.

When you need a replacement, latch onto the latest design pin. It's on page C-10 of TM 9-1005-223-20 (May 67), under FSN 1005-921-5248. It can be spotted in a flash. The tip is shiny chrome-plated and the rest of the pin has a dull chrome finish. The old pin, of course, is blackish.

This is a salected but of recent pubs of interest to organizational mainlenance personnel. This lat is compiled from recent AG Distribution Centers Bulletins. For complete details see DA Pam 310-4, Ch 4 (Dec 67), TM's, TB's, etc, DA Pam 310-6, Ch 3 (Apr 68), 5C's and SM's) DA Pam 310-7 (Dec 67), MWO'L

Light Bulbs

Here're the latest FSN's for Lamp, Incandescent, that goes in the extension light in your common tool kits. FSN 6240-222-0276 will get you a 12-volt, 25-watt and FSN 6240-153-6094 is for the 25volt, 25-watt. The new numbers are in SC 4910-95-CL-A74 (May 67).

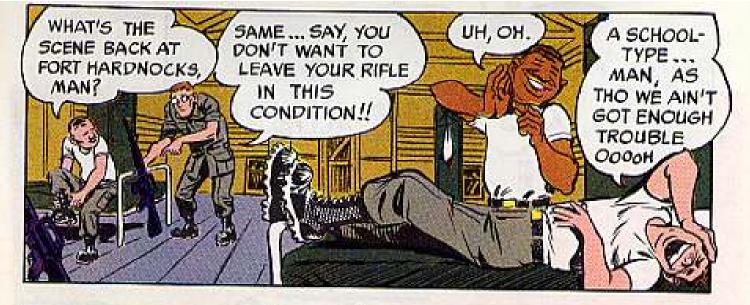

Chemical Items

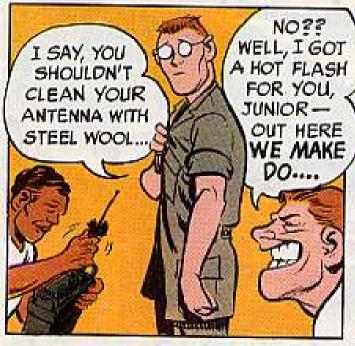

For identification and supply and publications info on chemical equipment see TM 750-5-15 (Feb 67), Chemical Weapons And Defense Equipment. The TM is loaded with pictures, too. It supersedes TM 3-500 (Apr 61).

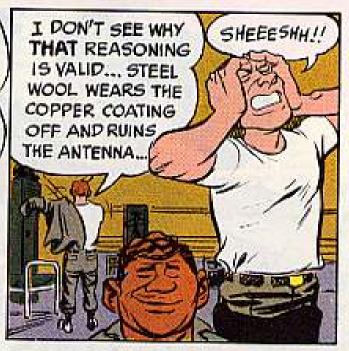

THE REPLACEMENT

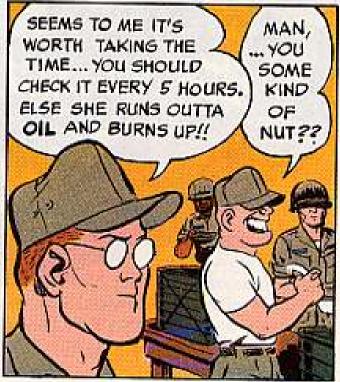

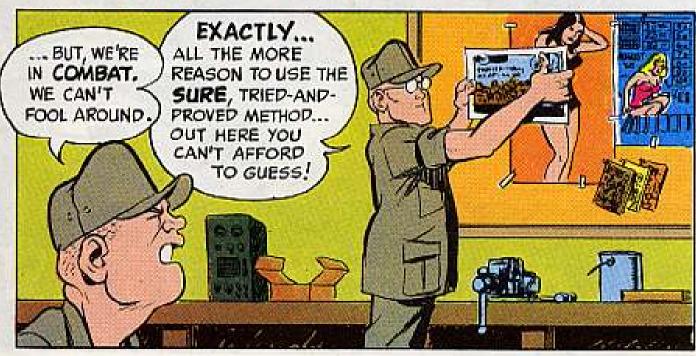

FOR EXAMPLE, YOU'RE USING THIS STREAM TO QUICK-WASH YOUR TRUCK... VERY SLICK, EXCEPT MUD AND GRIME'S GETTING INTO YOUR BRAKES AND POSSIBLY THE WHEEL BEARINGS, TOO.

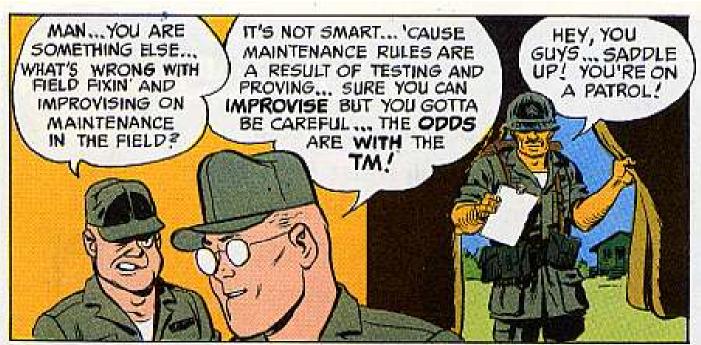

BE SURE-I MAINIEN ANCE

In takin' a Boonie-type tour
The PM you pull must be SURE!
When your life's invested
Don't try the UNTESTED

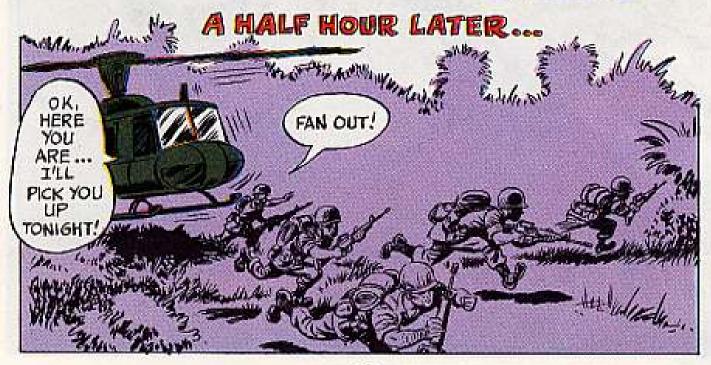

And, man, you'll be combat secure!

WE HAVE THE WORLD'S BEST EQUIPMENT ... Take care of it

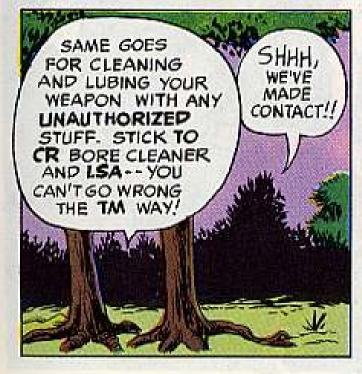

You say you're tackling a maintenance problem in a radio set?

Fine... but don't double your trouble by goofing up your test set, like the AN/GRM-55(), by pushing the MX-4622 test prod into unexplored test points.

Like, before making tests in the A-1 module in a RT-505/PRC-25 receiver-transmitter, make sure J2 and J3 jacks have correct DC polarities . . . +100 volts for J2 and -35 volts for J3 when checked on 100-volt range of the AN/URM-105 multimeter.

'Cause, if there's a whopping big difference in these voltages or in the polarity, your GRM-55's probe diodes will be damaged. Small voltage variations due to input power may exist, but polarities must be correct.

So, if this voltage polarity differs or if the voltages are much higher — replace the A-1 module with a good one.

And, see to it the function switch is in C position before touching the test set's probe to the RT's A-1, A-9, A-11, A-16 or A-17 module.

High voltage applied while the GRM-55 switch is set on A or B position could damage the test probe diodes, and knock the whole tester's calibration out of kelter.

If you wind up having to replace the prod, return the test set to higher echelon for repair.

An unchecked emergency radio set can be just about as bad as a brightly painted fire hydrant that rusted up inside and couldn't be opened when the fire alarm sounded.

O' course, you hope you never have to use that AN/URC-10 or ACR RT-10 radio set . . . but, when it's needed it's good to know you're in contact with rescuers and not just talking to yourself.

So . . . like it says in TM 11-5820-640-15 (May 67), put it to the periodic AN/URM-172 test set test.

The test set procedures are covered in TM 11-6625-1698-15 (Oct 67).

LUBE LOOSELY, NOT LIBERALLY

Seeing blotches on a movie screen and they turn out to be dripping oil in your AQ-2A(1), (2) motion picture projector set can raise the ire when you're trying to make the scene.

Sure . . . that AQ-2A(1) needs lubing, like it says in TM 11-6730-201-10 and -20, but not a bath.

Like in the central oil cup, you put a couple or three drops . . . and then, only when it's needed. The felt will stay soaked and that's all you need.

Too much oil can make for a real dust catcher as well as ruin the insides of the projector, especially the motor.

So, oil when needed . . . never overdo it.

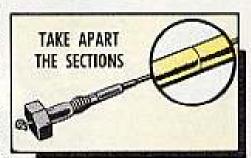

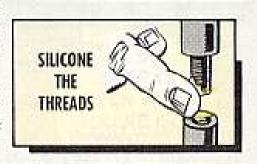

JOINT EFFORT

In case you haven't heard, it sure pays to take apart the sections of your whip antenna—such as the AT-912 and AS-1729—now and again to keep them from acting like they're welded at the joints.

But there's more to it than just taking the sections apart and putting them back together. What you want to do is put some silicone compound on the threads before you join the sections. You'll find an 8-oz tube of the stuff on page 4. 79 of Fed Cat C6800-IL (Jul 67). It comes under FSN 6850-063-1858.

If you're in a wet place, it doesn't hurt any to pull this kind of maintenance every day. Otherwise, once a week is a good deal.

ANTENNA'S A MUST

Whoa . . . Don't hit that mike button unless the antenna is connected to your AN/PRC-74() radio set.

WHY ?..

A fired-up transmitter without an antenna hookup will burn things out mighty fast.

So, just make sure your AS-1887() PRC-47, slant wire or dipole antenna is tied into your set before turning the OFF-ON-TUNE switch to TUNE.

And, do like it says in TM 11-5820-590-12 or -12-1 for making the antenna connection.

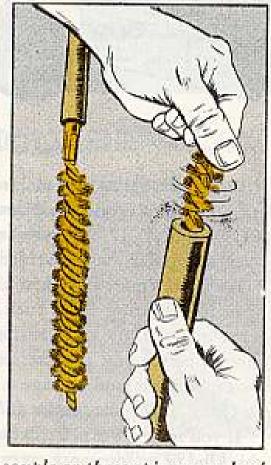

MEAN TO CLEAN

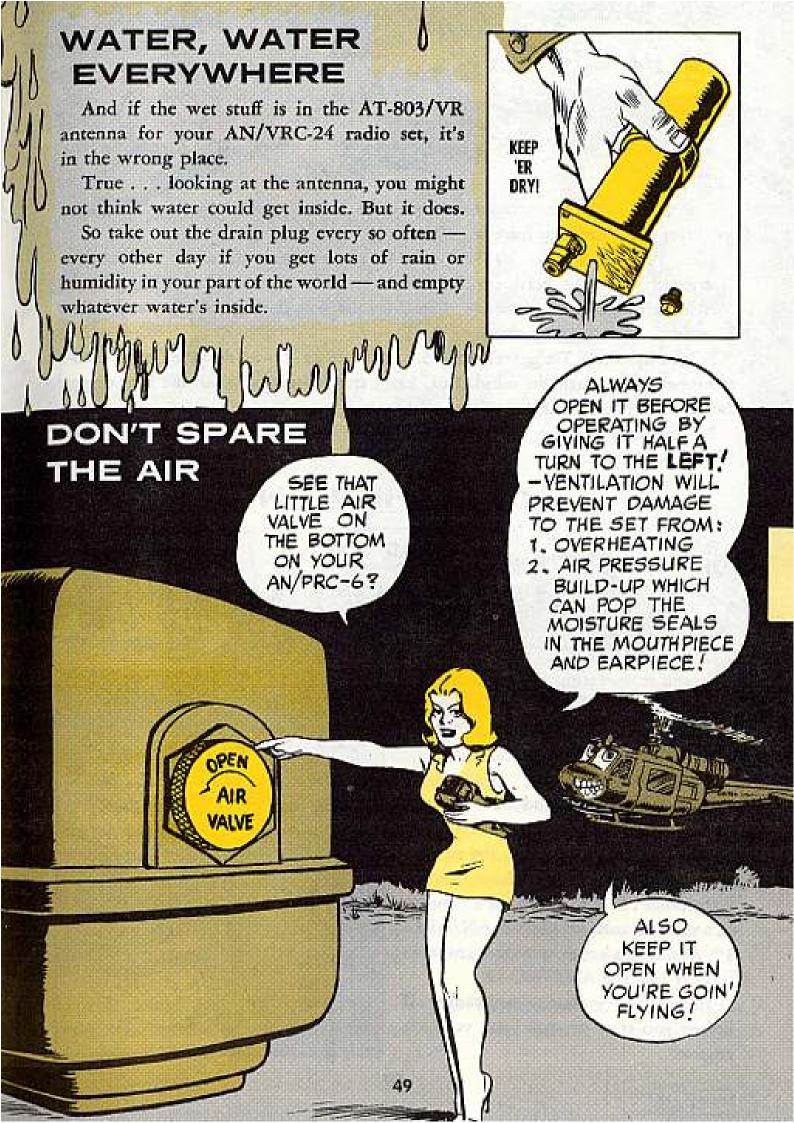

We had trouble getting dirt and corrosion out of the upper end of the AB-15/GR antenna base . . . that is, until we latched onto a .30-cal brush.

Using an old small arms bore cleaning brush (FSN 1005-556-4174), we ran it around inside the antenna section to get 'er clean. The brush works well by hand or on an electric motor, and really puts dirt on the run.

> SFC DALE SHIVERDECKER FT KNOX, KY

(Ed Note - Sounds good . . . and it takes only a couple or three spin-arounds of the brush to get the job done.)

Like, f'rinstance, that RT-524 or -246 receiver-transmitter . . . Make sure that input voltage is between 22-24 volts when there's a lot of talking to do.

A lotta transmitting at more than 24 volts will damage the set, and below 22 volts is not enough power.

Normally, the RT's geared for 25.5 volts, since it was designed with 9-to-1 receive-transmit ratio in mind. But, extra transmitting can put the heat on and damage the equipment.

No matter what your voltage rate is, never key the transmitter for more than 15 minutes at a time.

OFF, THEN ON

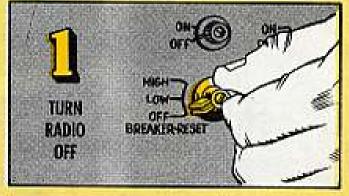

So you're operating your vehicle with its radio set on. But what do you do when your turn off the vehicle's ignition? Leave the radio on?

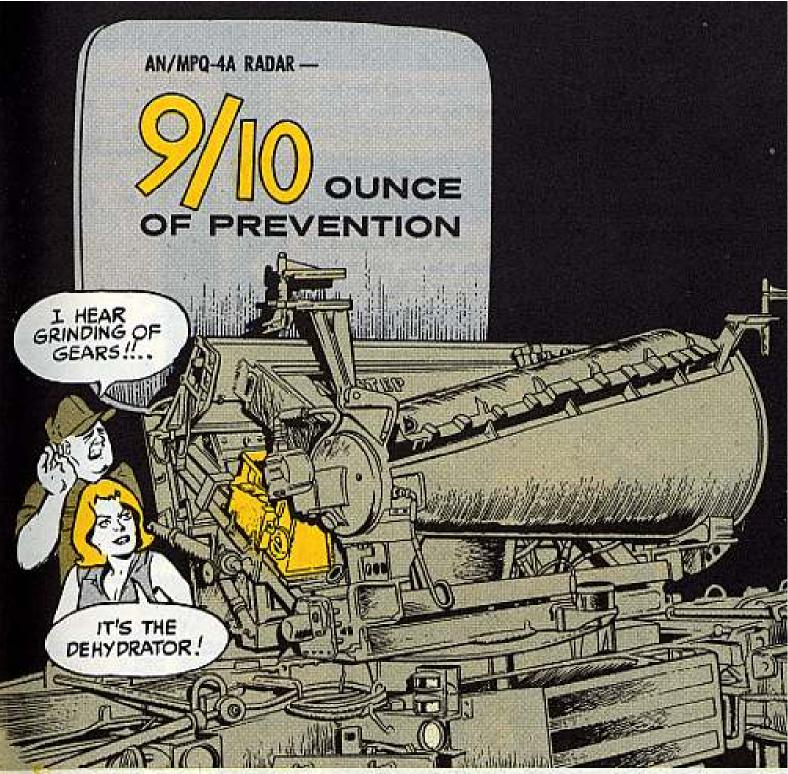

That's bad, real bad.

If you haven't found out already, when you leave the radio on and then turn the ignition off or on, the sudden surge of power can give the radio fits. F'rinstance . . . it can ruin the filaments in a vacuum tube set like the AN/GRC-19. And it can knock out the transistors in gear like the AN/VRC-12.

Remember — Turn your radio off before you start or stop your vehicle's engine.

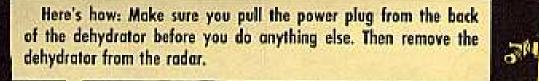

You . . . there with the AN/MPQ-4A radar set.

You'd better lend an ear so you can learn how that HD-264 desiccant dehydrator might lower the boom on the beam of your radar set.

You know the dehydrator's mounted on the antenna group and it's there so the RF waveguide sections will get dry air under pressure. That's needed so you won't have arcing of those beams or no beams at all.

A sure way to put your dehydrator out of commission is to forget about the oil in the motor and compressor assembly. You've got to check that oil as well as change it.

You change the oil in the gear box every three months or 500 hours of operation, whichever comes first. But, if those gears start making more noise than usual, you'd better check the oil level right now.

Now mark and disconnect the air hoses, take the two desiccant containers out of the cabinet.

> Next remove the two wiring clamp loops that secure the motor wiring to the air intake filter bracket.

Remove the motor and compressor assembly from the cabinet. You won't have to disconnect the wires if you're careful.

There're four mounting bolts that hold motor and compressor assembly to bottom of cabinet. Remove them. It's easier if you take out the front ones first.

Shift compressor end of assembly to one side and lift up. Easy does it.

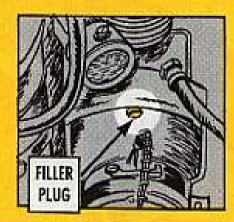

Set the assembly on something flat. Now take a look at the back of the gear box. You'll find three screws in the back arranged like a triangle. The top screw head's smaller than the two lower ones. The top screw's the oil level screw.

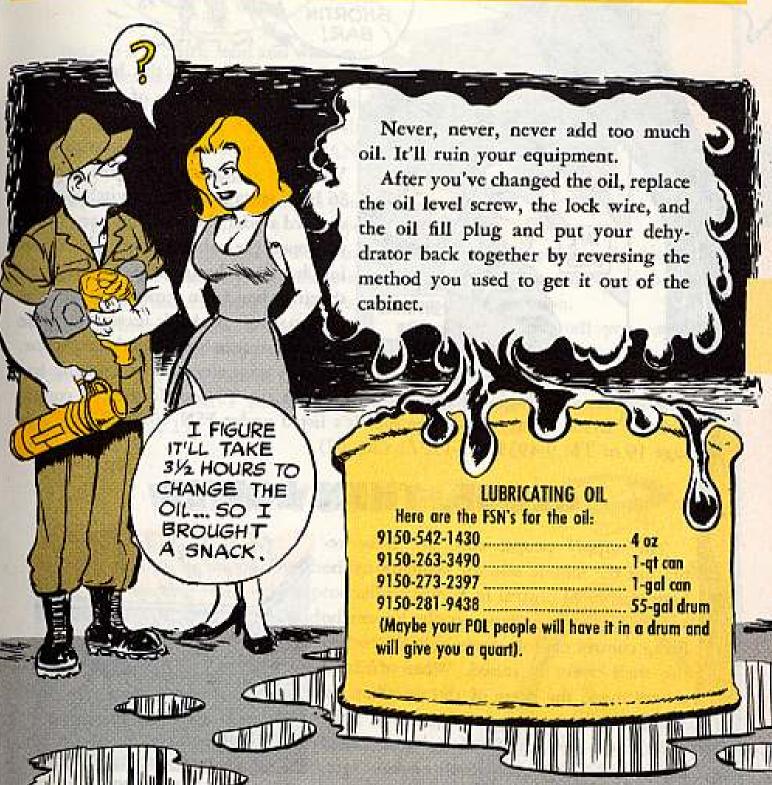

Take the lock wire off that goes through the screw head and remove the screw. The oil level should be up to this screw hole.

CHANGE OIL

To change oil remove 3/8-in plug on battom of gear box. Use a 5/32-in hex head wrench, FSN 5120-198-5392. It's in both No. 1 and No. 2 Common Tool Kits. (It's Key Set, Socket Head Screw).

After draining, replace plug. To add new oil, remove the 3/8-in plug on top front of gear box (you can use the same hex head wrench). Add 26 cc or approximately 9/10 ounce of MIL-L-7870 Lubricating Oil, General Purpose, Low Temperature.

ONE AT A TIME

Maybe you're good at doing two things at the same time, but forget it when it comes to moving the standby and designate switches on your Hawk launcher test set to ON—like when the missiles are on the launcher.

Seems that when you do this, the K40, K41 and K42 relays in the azimuth distribution box get energized at the same time with 208 VAC. This means arcing across the relay contacts and a chance of a short circuit that can give accidental missile electrical power unit and hydraulic arming.

So let the standby lamp come on before you flip the designate switch to ON—even though there's nothing in your publications that say you should.

WHO'S INSULTING
YA?!.. I JUST SAID,
"EVEN IF YOU ARE
AMBIDEXTEROUS, YA
STILL GOTTA DO 'EM
ONE AT A TIME!"

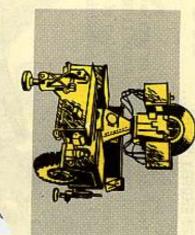

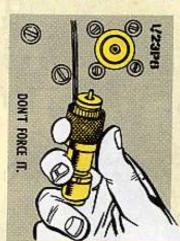

CONNECTIONS

mot—the J2 connector for the magnetron power supply and J5 connector for the modulator power supply in your Hawk AN/MPQ-37 range only radar.

When they're made, bakelite sometimes runs into the center conductor clip. Then the male plug won't go into the connector. And you sure don't want to try to force it in.

The thing to do is check the connectors. If you can't pick out stuff that doesn't belong in the conductor clip, you can figure the connector is no good. If there's nothing in the connector and it takes the male plug with no sweat, you're home free.

MORE

Here are the conditions under which an engine will labor or made to run above 225°F is a sure loser. heads the list. An engine subjected to excessive heavy Overheating due to an inexperienced operator

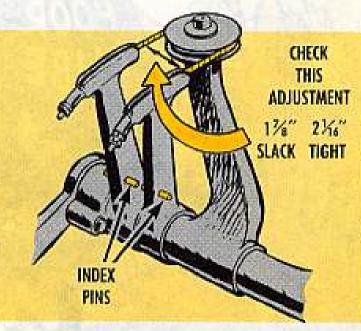

59

2. Operating with tracks adjusted wrong. Tracks on M107, M110 and M578 should be adjusted like shown in Fig 63, Ch 2 to TM 9-2320-238-10.

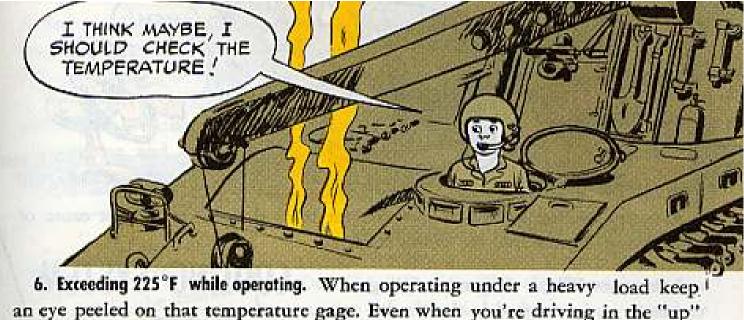

3. Operating with brokes adjusted wrong. If you suspect your brakes are dragging or pulling to one side, have your unit mechanic readjust them like it says in MWO 9-2300-216-30/1 (Mar 64) and TM 9-2300-216-20, para 39a, or TM 9-2320-238-20, para 51a.

- Check cable slack and tight adjustment as given in MWO.
- (2) With brakes released, index pins should line up at "release" mark.
- (3.) With fully applied brakes, index pins should be between apply and adjust and still be alined.
- (4.) If pins are not alined, or go to or beyond adjust mark — re-adjust brakes.
- 4. Moving out without a properly warmed engine. Always, but always, warm up your engine before moving out. When the engine catches good and runs smoothly, set the hand throttle control to run between 1000-1200 RPM. Run for about five minutes until the temperature gage begins to rise. Coolant temperature should level off between 170°-185°F. More details are covered in Ch 7, TM 9-2300-216-10 and para 16a, Ch 2, TM 9-2320-238-10.

5. Stopping without cooling engine. Before engine shutdown, make sure your coolant temperature is between 170° and 185°F. If it's higher, set your hand throttle and idle between 1000 and 1200 RPM. This should bring it down to the right temperature range. If it takes longer than five minutes to cool off, then you better check out the engine like it says in Table II, item 7, TM 9-2300-216-10 or item 7, Table I, TM 9-2320-238-10.

position through the open hatch, glance at that gage often.

GAGE CREEPING UP TO 225°? ... AND RUN AT FAST IDLE -(1000-1200 RPM) UNTIL COOLANT DROPS TO 180° F.

7. Exceeding Maximum RPM. Never, but never go beyond 2450 RPM. If your governor is adjusted right, this can't be done except on steep down grades. So watch it on the down grades. Stay in 2nd and use your brakes to keep below 9 MPH.

> USE YOUR BRAKES.

> > MAYBE I SHOULDA STOOD IN <u> 2ND.</u>

8. Excessive low idling. If you must idle, set your hand throttle to fast idle between 1000-1200. Never idle for long periods below 1000 RPM.

overheating. Here's how the causes stack up A faulty cooling system or low coolant level is the next biggest cause of

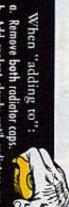

COOLING SYSTEM

system thoroughly. Place special emphasis on the radiator outlet hoses, manifold hoses and the water pump inlet

hose. Keep the bolts and hose

connections tight.

To prevent air pockets always . . These air pockets become heat traps. causes air to be trapped in the system. 1. Improper filling. Improper filling

- Add coolant slowly until radiators are water to a hat engine. filled and keep in mind—never add
- Replace both radiator caps.
- Run engine at least five minutes at 1000
- Recheck coolant level.

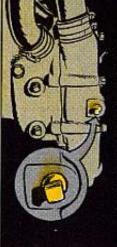

CHECK THESE

When "refilling"

Remove both radiator caps.

TRY UP-STREAM WATER HERE

- When full, bleed any trapped air off by down the plug when water and no air hole in the thermostat housing. Tighten removing the vent plug from the vent comes out of the vent.
- d. Refill the radiators and install the caps.
- Run the engine at 1000 RPM for fiv minutes and recheck the coolant level

stepping on and damaging the caps, paint a a new one . . . FSN 2930-690-2701 (P/N PSI. If either one of yours is bad, replace it with keep the cooling system pressurized to 14-17 2. Faulty radiator caps. Radiator caps should "no step" caution on the deck nearby. 10866042). To discourage crew members from

3. leaks. Inspect the cooling

pound used is FSN 6850-598-7328. A set of clogged radiators like it's spelled out in TF cleaning instructions come with the compound clogged cooling systems. The cleaning comroutine job; it's used only to clean rusted or Ord 651 (Apr 64). This cleaning job is not a 4. Clogged radiators. Flush or clean internally

cooling system takes about 71/2 cans. 6 ounces for every 12 quarts of water. A 22-gal sion Inhibitor, FSN 6850-753-4967 (6-oz can). Use After a flush or cleaning job, always use Corro-

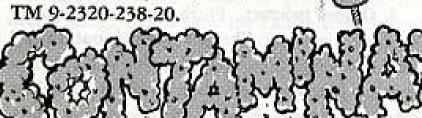

cleaned at every Q-service when the power pack is out. partment. Vehicles in Southeast Asia should have their radiators removed and external clogging to a minimum, don't let junk accumulate in the fan comand air under pressure; or have your support steam them clean. To keep If your radiators are clogged externally, blow them out with hot water

Use FSN 6620-846-9848 to get new ones. Your to replace them if you find yours are faulty. -20 TM shows how they're replaced 5. Defective Thermostuts. The only thing to do is

6. Broken or improperly adjusted fan belts. The belt tensioner should be adjusted to have a 1/2-in clearance. That's how its shown in Fig. 74, TM 9-2300-216-20 or within "Operating Range" as shown in Fig. 72, Ch 1, TM 9-2320-238-20.

If the belts are badly worn or any one is broken, replace the whole set. They come as a matched set (4 belts). Order Kit, belts V: fan, FSN 3030- WAFF 780-7001.

1. Dirty filter pac. Cleaning the filter pac is a daily after-operation job. Let that pac go dirty, and you're asking for trouble. In severe dusty operation, you may have to clean them several times a day. The right way to remove and clean the filter pacs is spelled out on page 110, TM 9-2300-216-10 and pages 97 and 98, TM 9-2320-238-10. You can shake, use compressed air or wash those filter bags; but before you do any of these, read over the instructions given in the TM so the job will be done right and the filter won't get damaged. And above all, be certain to clean out the filter pac compartments.

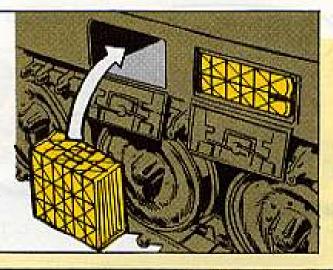

Misalined filter pac. Are your filter pacs installed right? The installations shown in these TM illustrations are wrong and have been rescinded.

Fig 61, TM 9-2320-238-10

Fig 85, TM 9-2300-216-10

Check your pacs now. They should be installed as shown in these changes . . .

 The correct installation method is to install the filter pac assembly so the basket "handles" face inboard. In other words, the "handle" end of the basket goes into the compartment first. In case you can't find the FSN for the filter pac, it's 2940-751-7090 (P18868).

3. Leaky intake air ducts. Look for loose clamps, misalined parts, holes or anything that looks like it'll let dirty air sneak into your engine's induction system. Dirty, unfiltered air can chew your engine to bits in a short time.

CKREEK

LUBRICATION

1. Low oil level. Check your engine oil before and after every operation. The level should not be below the FULL mark. After an overnight stand the level may creep up to 1-3/8 inches above the FULL mark; this is OK.

2. Clogged lubrication system. If this is the case, change the oil filter elements (FSN 2940-555-6348), clean out the filter shells, drain the contaminated engine oil, fill the engine with OE 10 and run from three to five hours. Repeat the flushing until all the sludge is washed out of the system. When it's cleared, again replace the oil filter elements and fill the engine with OE 30.

3. Wrong grade or diluted engine oil. LO 9-2300-216-12 and LO 9-2320-238-12 specify OE 30 for expected temperature above + 32°F and OE 10 between + 40°F and + 10°F. The use of a too light weight oil, either the wrong grade or the right grade diluted with fuel can cause engine overheating. A situation like this can be spotted by a low oil pressure reading on the instrument panel gage.

YOU ASKED IT -- NO GASKET

Dear Half-Mast,

Is there supposed to be a gasket inside the cover on the intervehicular cable that sends electrical power from a truck to the trailer it's pulling?

55G N. D.

Dear Sergeant N. D.,

You bet not. If you come across what looks like a gasket inside a trailer receptacle cover, it's a homemade job. With a gasket inside the cover, and the cover shut, water and stuff can get inside through the indexing slot. The spring keeps the cover tight against the connector, without adding a gasket—believe it.

The receptacle on the truck is another story. It's made in a different way . . . so the cover needs a gasket.

Halk-Mast

BRAKE BETTER THAN BREAK

Never let it be said that you didn't know because here's the word now—when you park your multifuel or diesel truck, make sure the gearshift is in neutral and handbrake on.

Why? Multifuel and diesels are compression ignition engines, that's why. So with the transmission in gear, the engine can be turned over and started by pushing the vehicle. And an accidental push could mean a repair job for anything that might get in the way of the vehicle—like people and things.

In other words, use your parking brake when you park your multifuel or diesel truck. Never . . . never . . . NEVER park with the transmission in gear.

Get the sequence right . . .

1 Replace seal . . .

3 Put cup into element and remember the small end of the cup points down.

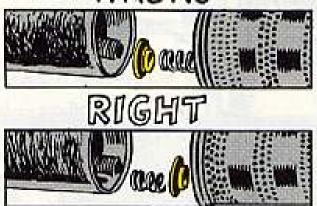

CUP AND SPRING NEEDED

Did you remember to put the spring and cup in the filter—along with the new element? Without the spring and cup, the element is loose in the filter. And this means it can't do its filtering job.

WRONG

And remember, too, the small end of the cup points down.

ENOUGH TO SEND
THE VERY REST

WATCH YOUR

REPORTABLES...

No if's, but's or maybe's, friend — equipment status reports must be accurate!

For one, your reports pack a big wallop when it comes to Uncle deciding how you and your buddies will be equipped tomorrow. For two, the reports call the signals on supply support plans for unit equipment.

'Nuff said, right . . . ?

The first things you have to latch onto are SB 700-20 (Apr 68), Adopted Items of Materiel and Reportable Items, and AR 711-5 (Dec 67), Army Equipment Status Reporting System (Materiel Readiness). You'll also need your local SOP on equipment status reports. All 3 pubs you should know real good.

And, right now here's some handy know-how to help you crank up a good report.

THE SCOOP ON REPORTABLES

Reportable items used to be reported in AR 711-140. You can forget about 711-140 now. It's been replaced by SB 700-20.

In SB 700-20 the reportables are tagged with a Reportable Item Control Code (RICC). And, an item's RICC tells you who reports it. For example:

RICC 1, 2 and 6 items are reported by both Active and Reserve outfits.

RICC 3 and 7 items are reported by Reserves only.

For a complete rundown on the RICC's, see para H-7, AR 711-5, or para 4-h, SB 700-20.

Your property book (PB) page for reportable items must be flagged with a 1/4-in red circle in the authority block, like it says in AR 735-35. The flag makes it easier to spot reportables when you're making out the report.

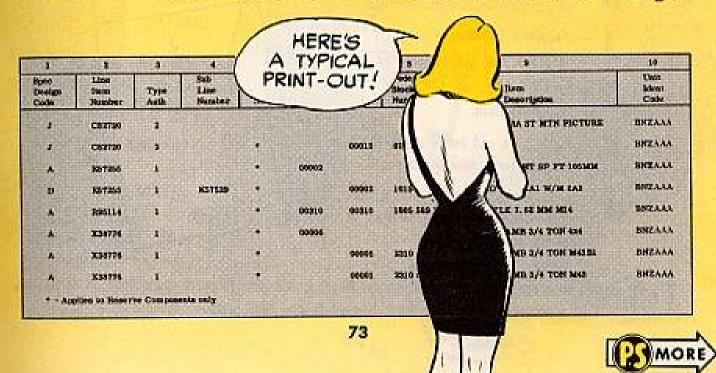

And, remember, reportable status will change on items from time to time, so keep a real close check on changes to SB 700-20—and fix your flags as needed.

SB 700-20 is being used quarterly - every 3 months. Get the latest!

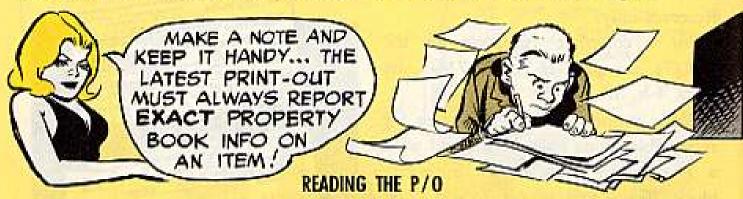

THE REPORT

Normally, your support outfit will provide a machine print-out (P/O) of your unit's equipment status report. Then it's up to you to update the report as changes occur, and have a report ready to go whenever its cut-off date rolls around again.

CROSS-CHECK THE P/O

And, it's always best to double-check the print-out against your property book before you shoot in a new report. That'll help you to review the previous report for accuracy, and will protect you against any goofs that may befall the machined print-out, elsewhere. After all, once you turn your report loose, all your facts and figures are fed into automatic data processing machines. And, once a machine goof sneaks in, it can be repeated over and over and compound all kinds of problems . . . until it's caught and corrected by a human type.

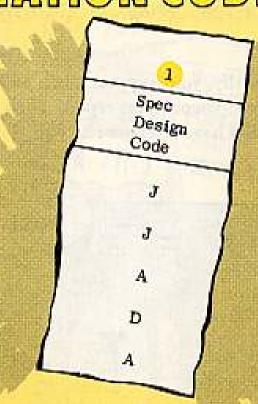

The machine print-out, of course, talks mostly in codes and uses columns. The columns may line up differently on different print-outs, but the info recorded on all print-outs is pretty much the same. And, the column headings and coded info that concerns you the most read like this:

SPECIAL DESIGNATION CODE

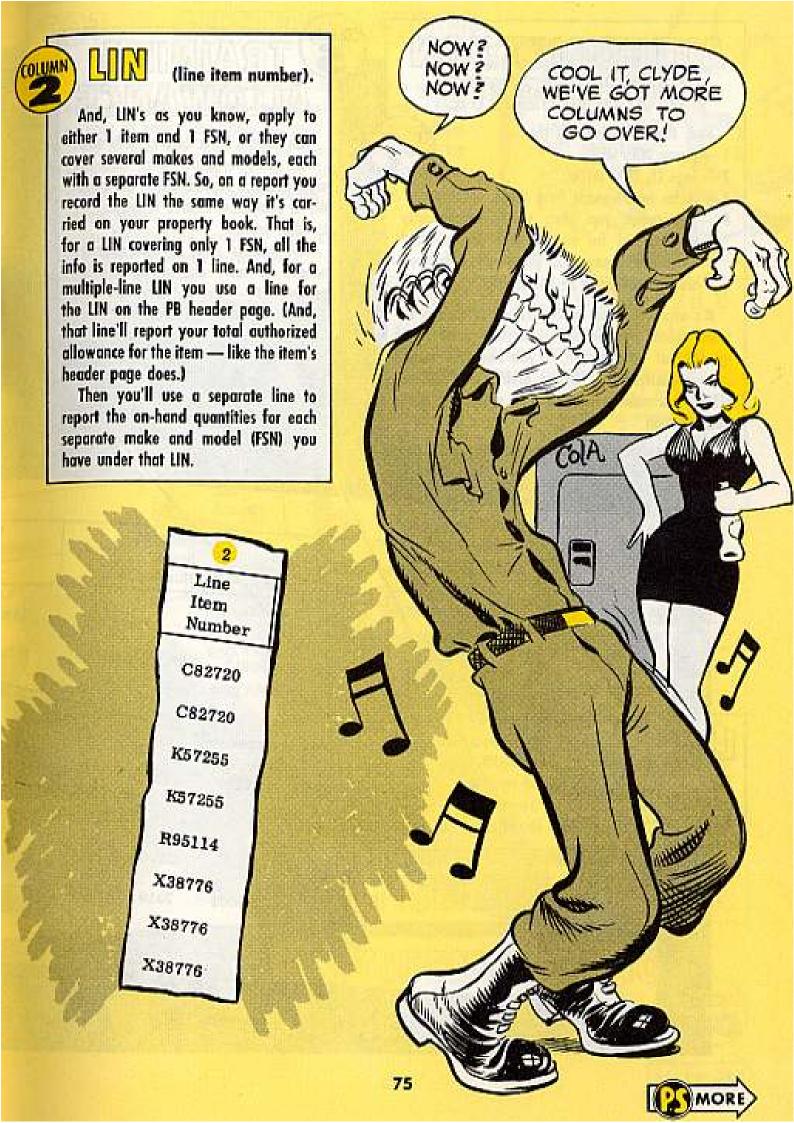

This code tells what kind of equipment an entry is reporting. For example, a capital —

- Means organizational property (It's in your organizational PB).
- Identifies installation property (Items in your installation PB).
- Says it's a substitute item.
- Reports an old series radio that's subbing for a new series radio.
- Is for Reserves only, and reports unit-owned equipment located in an equipment pool.

These codes are mighty important in fitting all the pieces together at topside, so bone up on Appendix H, AR 711-5 and learn 'em all.

AUTHORIZATION

And, they're coded like this

- 1 Means TOE / MTOE.
- 2 Says TA, TDA/MTDA.
- 3 Is for maintenance float items.
- 4 This covers you when you're momentarily embarrassed for authorization for on-hand stuff is waiting to be turned in. quantities. It says that previously authorized

quantity of an item. So, if you have the same MTDA, you make a separate line entry for each item authorized by TOE or MTOE, TA, TDA or know what authorization document gives what authorization. It's also important to the wheels concerned to

ITEM DESCRIPTION

UNIT IDENTIFICATION CODE (U.I.C.

THAT'S THE P/O

As you can see there's nothing mysterious about P/O code talk. After a few passes you should be able to translate the scoop in nothing flat.

The other columns you'll find in a print-out are self explanatory, or else they provide routine info for your supply support outfit.

ABOUT SUB ITEMS

It's possible to have 3 different situations when it comes to substitute items.

FOR EXAMPLE...

- Normally you'll have a reportable substitute item in lieu of an authorized reportable item. In that case you simply report both items, on separate lines.
- But you can also have a nonreportable substitute item in lieu of an authorized reportable item. When that happens you report info on the authorized reportable item only.
- And, when you have a reportable substitute item in place of a non-reportable authorized item, you report the reportable substitute. The only info on your report relating to the authorized item is its LIN, which you put in Column 2.

REMEMBER
WHEN YOU'RE
REPORTING
SUBSTITUTE
ITEMS...

use the special designation code (D or R) in column 1, and check your local SOP for any special instructions on reporting sub items.

TECH REP HELP

78

If the publications leave you with questions, you can call on the U. S. Army Major Item Data Agency (USAMIDA), Chambersburg, Pennsylvania 17201. That outfit has tech reps visiting all commands and Army areas twice a year. Your outfit can shoot in a request, through its headquarters, for a visit by a tech rep. An AR 711-5 expert'll be around to help you check your print-out and property book, and he'll show you how to come up with an accurate report.

HEP GLAD YOU'VE GOT SOME QUESTIONS ON AR 711-5.

GLAD YOU SHOWED UP... I SURE HAVE.

Keep those DA 2408-3 entries short—but specific. A single line entry on DA 2408-3 for the periodic PM service includes any inspection time required as a part of it. So the only extra lines you need for the PM service entry are for adjustments, repairs or replacements directed by the equipment TM as part of the service—and even for these actions, manhours are included with the manhours on the PM service line. Lubrication and antifreeze entries are made on DA 2408-1 only—not on DA 2408-3.

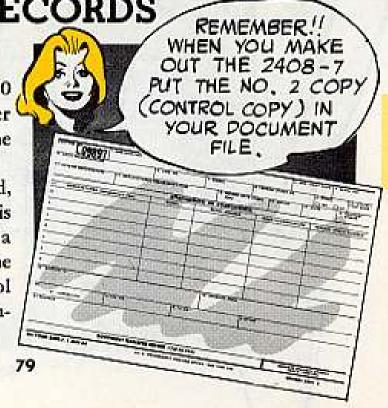

FLAME THROWER FEEDER

Maintenance records and gain, transfer and loss reports are lagging on the M4 and M4A2 flame thrower service unit (FSN 1040-740-1152 and FSN 1040-740-1150) — TAERS line No. 770630. So, start tattling, friend. See Appendices II, III and V, TM 38-750 for forms needed and the mailing addresses.

PB/TAERS RECORDS

Property Book Keepers note —
For items listed in App V, TM 38-750
(May 67), add the TAERS line number
to the item description block on the
property book page.

When any of those items are gained, lost, transferred, or their FSN is changed, you make out and submit a DA Form 2408-7, like it says in the TM's para 4-9. The form's control copy (No. 2 copy) goes in your document file.

WHAT DO YOU MEAN YOU DON'T KNOW WHERE TO STICK THOSE

CONNIE'S REMINDERS

Your military standard engine have a Connic decal telling you to keep that engine cool?

You can order 'em from

THIS ENGINE

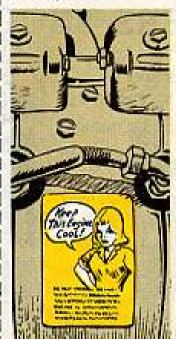

DO NOT INSTALL OR OPER: ATE IN LOCATION WHERE FREE FLOW OF AIR TO ENGINE IS OBSTRUCTED. DO NOT REMOVE ENGINE SHROUD WHILE OPERATING.

6-HP 4A032 series on top cooling shroud; 10-HP 2A042 series on top shroud; and 20-HP 4A084 on top shroud.

Clark 290M Hose

You order the front swivel and the tube-to-lift cylinder hoses for your 290M Clark tractor by manufacturer's code and part numbers. You'll find the hoses listed on page 32 of your TM 5-2420-206-20P (Jun 66). You have to match the numbers by the Line Numbers. Be sure to include Code 12603 with each part number. Line Number 4075, Part No. 565206; 4076, 565205; 4077, 565189; and 4082, 565146.

Administrative Storage

The new word on administrative storage of Army equipment is in TM 740-90-1 (12 Mar 68), Administrative Storage of Equipment. It supersedes TB Ord 1045 and TB 740-93-3.

Believe the Words

The right torque — but the wrong picture. That's the digging clutch adjustment story on Page 61, PS 185. The right parts to work on are like the words said: Numbers 6, 7, and 8 of Fig 39 from TM 5-3810-206-10 (Sep 63), and not the ones shown in the picture. If you torqued those setscrews 150 to 160 ft-lbs, you'd distort the shoes.

Yup. Don't Switch

In case any of you zapmen got confused by that item on switching M16A1 rifle bolts on page 39 of PS 187, let this set you straight. M16 bolts and bolt carriers can be switched at the direct and general support levels where they have gages and stuff to doublecheck fit and headspace, **but not** at the user level. For you, the wise word is still "Never switch bolts."

Multifuel Medicine

Leaky freeze plugs (even new ones) in your multifuel engine? Get your support to try sealing compound when installing. It makes 'em easier to install and then seals 'em. They'll want Sealing Compound, Type III, Mil-S-45180, FSN 8030-656-1426, 1 pint can, in Fed Cat C8000-IL-A (Jan 66).

Multifuel Special

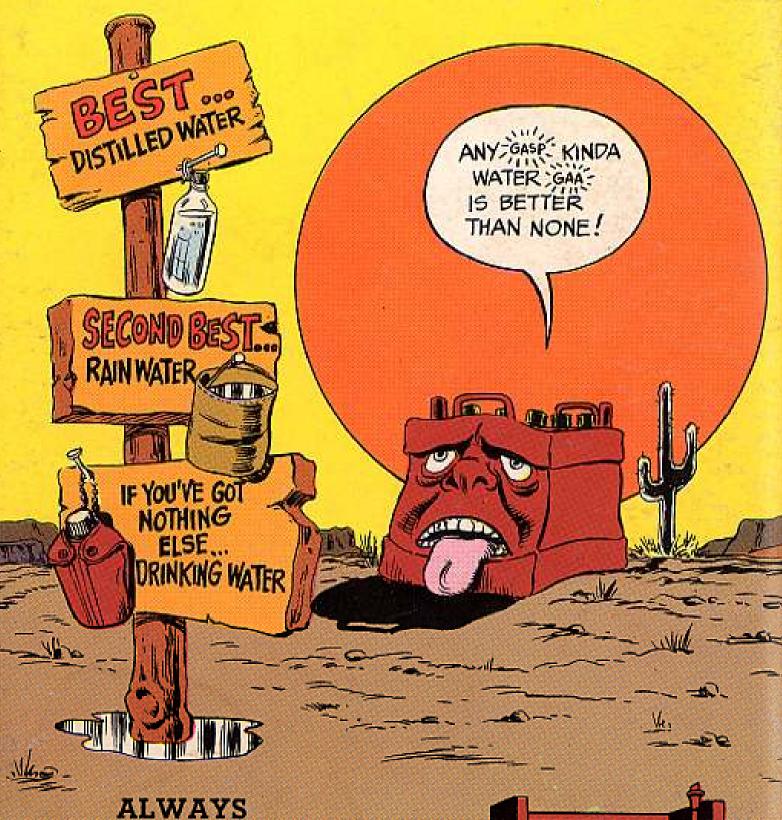

If you've got multifuel engine trucks on your ranch, you need to lasso a li'l critter branded as DA Pamphlet 750-11 (10 May 68). The Multifuel Engine Operator. Looks like it was lifted right out of PS! Copies are available from the AG Pubs Center, Baltimore.
