## WHAT ARE YOU DOING TO HELP THE COMMUNITIES?

*Executive editor . . . what a question.*

But don't go away so quick, son. Maybe it's closer to being than you think.

It's like this—we don't like to think we're downright together in the arena. But except that we have big advantages in mobility and firepower over tanks and hovercraft.

We think our main strength is based on our ability to test out more products than anybody else—the vehicles, the weapons, and the aircraft.

And we are so right.

For this equipment has to be reliable, flexible, and capable to do us any good. Every tank, and gun, and airplane on the desert has to be able to do the enemy's power.

As the Arabs say, with obvious meaning, "An enemy of my enemy is a friend of me." And that also works the other way. "What helps your enemy hurts yourself your enemy too."

A detailed tank, gun, or airplane is your enemy. It sets down your mobility and your firepower. It sets down your ability to move and it keeps you out down by enemy action.

## COUNT THESE TRUCKS, TRACTORS, MOTORS, AND MAINTENANCE

Do you know that your industry divisions need all these things to do a thorough job?

Anyone can plainly see that if you get half of 'em on wheels, you've got only half a division. And anyone can plainly see that shipping divisions in half automatically makes the war time job as strong.

And I can see. Can't you? It takes more than just good products to make us stronger than any enemy — it also takes good maintenance.

**TYPE  
IDENTITY  
Description**

- 3 electrical roof panels
- 3 electrical repair tools
- 2 interior repair tools
- 2 exterior deep tools
- 2 utility repair tools
- 1 deep equipment tool
- 1 two-pronged roller
- 40 covered wheels
- 20 cushions
- 20 back covers
- 10 4-in. deep tools
- 10 foam rollers
- 17 water tools
- 10 tool storage cabinets
- 7 4-in. deep tools
- 1000 1/4-in. wide (spiral)
- 100 3/4-in. deep tools
- 10 3/4-in. deep rollers
- 100 cushion rolls
- 20 3/4-in. deep tools
- 10 automatic gas savings
- 17 heavy tools
- 7 light tools
- 4 mopups
- 4 mops with buffers
- 1 air compressor unit
- 4 signal tape repair tools
- 1 wall cover repair tools
- 2 tool storage cases

## Combat

### UNCOMMON INTERCHANGE

28 Aug. 1954

Days Inn, North of Ojibway House

In the earlier edition of this M.M. Co., we've been able to get some items in plentiful supply but that is impossible to get other parts.

For instance we have been able to get GMC Front Spring Bearings O.K. as we have used them for Jeep ball-joint bearings by cutting off  $\frac{1}{2}$ " and drilling a groove back. For Dodge rear springs the bearing works O.K. by cutting off  $\frac{1}{2}$ ". Also we use them for the clevis ball-joints on the GMC's.

We needed a large size nut for covering a shell casing on our lathe, so we found out that the taper cones for Buick rear Brake Drum Leds may be used in size for the cones on our lathe by using adapter bushings furnished with brake drum lathes.

Also we found that the Case bearing of a GMC generator can be used to replace the bearing on the generator of Generaling Unit 17-50771-50 (20 H. W.).

In using our gasoline driven Oxon Battery charger we found that more batteries could be charged with economy by making two main charging lines off of the two high-charging-rate wires and two low-

## Maintenance Stories

try connecting on the side of the charging plug panel and then looking at either all 60-watt batteries, or 2 rows in a row and parallel, or all rows in parallel to those two main charging wires.

The way we had it figured is that instead of the current having to go through the releases on the plug receptacle, and then putting an extra load on the charger for each battery by taking the current from the quick charge connections, all the energy could be utilized for charging the batteries. I know the best way to hook up two 6-watt batteries in series, or one 6-watt with battery in three segments, but if you hook up several 6-watt batteries in parallel they will charge O.K.

Before that, we had a 60-watt tank generator-and-rectifier rigged up to an electric motor and put 4 6-watt batteries in series and with 4 or 5 sets of those in parallel.

I hope one of these ideas can be of value to you. If you want to get in touch with me while this is out, although, please write to my home address till I get settled on location in the U.S. You hear in Korea since July 1964.

PO Box 11, Hoop, P.O. 32677  
1101 Oak Avenue, APO 963  
San Francisco

### TOO LITTLE AND TOO LATE

Editor, *PO Magazine*  
Bardon Pressing Company, Ltd.  
Dear Editor,

8 Sept 1961

Let's don't neglect 40 and 200-watt-hour maintenance, it will save us in the long run. I remember a real experience back in 1944 and 1945 in both ways the good and the bad of knowledge. I was a Canadian

Mount Fuji was in a medium field artillery battalion. We were on the main road of the line and had barely enough vehicles for the job. After we lost a vehicle, the Battery had to load their "inventory" on other tracked vehicles and numerous equipment had to be discarded. Ordnance had more work than they could do, so we neglected our fuel vehicles and ammunition deliveries, replacing engines, transmissions, valves, etc. I know my way doing the wrong thing, but we kept our vehicles rolling. I thought that we could get by with a little less fuel vehicle maintenance for a few weeks. The fighting got a little rougher and we had to stay on for longer. Finally, we pulled back into a war area. After we got medical stores, most of the boys were trying to find a clean toilet to use as piss. I decided that we should pull a few vehicles and have a quick look at the heavy ones. One that did it. The "old man" seemed a couple of times and all the maintenance that did an about face and wanted looking for repairs. We had every man in the battalion who had any looked like a mechanic, doing mechanic's work. The brake shoe linings were gone, the brake drums were worn down so much that they could not be refixed, the brake shoes were worn, the disc to be caused down, the wheel bearings were dry, the brake wheel cylinders were empty, the rear spring was broken, the springs were dry and frozen, and the universal joints were dry and easy as about 75% of our vehicles.

We all, from the Battalion Commander on down, learned a lesson, but what a lesson! and costly one. It was all due to fuel vehicle maintenance neglect. The Battalion Commander ordered all (mechanics) and every every equipment and vehicles to help a fuel vehicle maintenance shop.

Major J. W. Worthington  
Headquarters 5th ASMD Div  
ACJS Ammunition Section  
Camp Chaffin, Ok.

## How To Time The Ignition On Your

# M46 TANK

## Without A Timing Light

When an M4 crew has to push out their tank engine, they usually go over a pre-empt test the timing, that starts something like this: "Mo, Jo, what magazine do I want on, right or left?" then "What's the breaker point gap setting?" One says, "Set the gap at eighteen thousandths", somebody else says, "Set it at one and one-half thousandths". Then another says, "Yeah . . . should be eighteen plus or minus thousandths". Above the noise the ignition timing discussion's beginning to sound like the "Kawoog debate", a real tank humor like Sgt. T. G. Madson points along with an ignition setup and keeps the tank jockies from picking the bad wrenches out of their coats.

Here's Judge's method done by the numbers.

1. He takes out the engine/ignition plug so he can see the timing marks on the flywheel (Fig. 1).

2. Then he screws out all right spark plug and screws in a compression gage (40-110) (Fig. 2).

3. Then the transmission he removes the power-trail cover and sticks in an input-timing wrench (C17W 110, 184) (Fig. 3).

4. The large knows that its right place must be set in comparison with when timing the right magazine, so he turns the input wrench clockwise until the gage shows pressure in the cylinder, and continues turning slowly until  $\frac{1}{16}$  appears on the flywheel opposite the timing pointer. (Madson says, "Leave the flywheel pointer on this marking until both right magazines are timed and remember the right magazine are on your right when facing the accessory end of the engine") (Fig. 4).

5. Then on the magazine, he removes the cover screws and sets up the cover and

Fig. 3

wings the valves out of the way.

4. Now to loosen the nuts that hold the magnets to the assembly case, first rotate each magnet bearing until the timing mark on rotor magnet pole and "L" marks mark on magnet bearing are in line. (Fig. 4) (" disregard all other markings," Ferguson tells us. "The marks mentioned are the only ones that mean anything as far as points concerned.")

Fig. 4

5. When the marks are in line, then tighten the nuts that'll keep the magnets in place.

6. When the timing marks are in line, a 4-foot "foot and one-half" (approximately) feeler gauge should have width of gap when pulled from between the breaker points. (Ferguson says to make it a CLEAN feeler

Fig. 5

gaps—in any case and the particles you can't see in, rubbing off the gaps with the breaker points will get you a dead magnetic force that you can split.) If you get the plug, the gap is OK. If not, loosen the screws holding the breaker assembly and move it up or down until the gaps get that drag that tightens both screws.

4. With both right magnet-breaker-point gaps at  $0.0017"$ , loop (think you might get confused to turn the input-wrench clockwise until the breaker-point

can follow) it on top of the tube that's just starting under the run follower. That'll open the points to their maximum gap . . . which is  $0.0017"$  plus or minus  $0.0002"$ . Check this maximum gap on a thin tube. If any maximum gap is not within the  $0.0017" \pm 0.0002"$  limit, the magnet isn't serviceable. Take it off and replace it with a new one.

10. After he sees and checks both right magnet gaps, he inserts a  $0.0017"$  feeler gage between one and then has the input-wrench turned counter-clockwise, one-half turn.

11. He now pulls slightly on the gages and tells his helper to turn the input-wrench clockwise slowly. "For perfect synchronization, both gages must come out of the gaps at the same time, if they don't, loosen the stage mounting nut and move the bearing slightly until they do," says Sgt. Hoffman.

12. After he synchronizes both right magnets, he checks the screw gaskets, puts them and the screws back on the magnets and screws them tight, and makes all cables that he processed.

13. He removes the compression gage from the right spark-plug hole and puts the plug back in.

14. Now the left magnets, he gets over the input-tuning wrench slowly, clockwise (about 1 turn) until the ignition timing mark (10) appears opposite the engine pointer and leaves it there until he checks both left magnets.

15. From here on he uses the same procedure as for the right magnets.

16. After timing the left's stage, he takes out the input-wrench pins on the screws and screws in the engine inspection plug.

# Hand- Tool CLINIC

THE LOWLY SCREWDRIVER  
AND HOW TO USE IT

IF THESE THINGS  
FLUPPH

HOW TO LAUNDRY

1. Hold the  
screwdriver  
at a 45-degree  
angle to  
the hole.

2. Push the  
tip of the  
screwdriver  
into the hole.

SEE YOUR LOCAL  
HARDWARE STORE

**HERE'S  
WHAT'S  
WRONG**

You've been using it for a **HY-BID**, haven't you? You've hardened against wearing. The handle is, for auster, it breaks.

**SO.....**

**USE A PRY BAR**—it's made for prying, strong enough to resist bending. If you must use a crowbar, use good weathered steel judgment.

**CHARACTER** on a screwdriver can bend the shaft, mushroom the end, snap off the blade... and make the handle slip, or split it.

Your **CAN TAP** on a screwdriver that has a shaft going off the way through the handle. Watch for the plastic handle... Some can take tapping, some can't.

The wrong screwdriver for the job... the screwdriver/breakdown's in the open slot.

Use the correct size on the blade makes a snug fit in the slot. You'll do the job faster and easier.

**END REPAIR SLABS**

2. Keep the ends of fiber very tight, but taper as high as possible.

4. These balls like a fiber break off very easily.

**DON'T USE BIRTHDAY CANDLES**

Not Good This

Not Good This

### *Take me to the bank*

I don't think I'm getting too far's out of my rotation in testing that Herman didn't actually get a "boom" engine for his test engine last week, regardless of what he says. As a matter of fact, it just runs better, and I'll tell you why. When the shop happened to be off the deadline and jacked the engine, they forgot to check supply, and ran through what they did, there was no replacement. So the engine's chain was rolled back on deadline and it ran there until the new plane arrived. Now Herman is bragging that his new engine is "boom" because it runs around 200° instead of the old 180°, but it actually doesn't run any better or pull as good.

The real pump of the matter lies in a chemical formula which deals with mi-

lition of materials in testing. A nice technical film of mine was formed during the war, which keeps Herman's engine best cooled in, instead of being transferred to the air.

If the jury believes in the shop had used some knowledge and plugged the engine's engine and filled the engine during testing, I would not have had to make this Monday morning prediction that Herman will soon be making another engine if they don't shut his workshop testing system.

### *Storing Batteries*

And while I'm talking, what's with you of stored batteries? Couple of cardinal rules here—the most important in keeping them in a place that's given by

dry, cool and clean. That is, the dumper and warmer the climate, the faster your batteries up and do.

Find time to build some storage shelves deep enough to clear the posts and open enough for air circulation. There's about exchange give too, while we're at it. Right here the charge has will average about a point a day at normal (70°F.) temperature, but less or less at lower temperatures—much more than normal. So I get myself a quart—largest size much of a better charge to give and have when needed the data on each battery under the charging duty and processed them with age.

### *Temporal*

Here's a thing you can skip in the future to lighten your burden. It was even all water-proofed vehicles with the latest systems (12, 14, 16, and 2000). Up to now you've had to scrape off the water-proofing Temporal to get at the battery terminals and caps and things, and then slip on some more Temporal when you were through delving. Well, from now on if you have no scrape off the goop, leave it off.

Vehicles coming out of production don't have their batteries coated with Temporal anymore—the water-proofing compound will be supplied in the shop

water-herding like internal batteries will be coated with the stuff just prior to finishing, and in the meantime, working.

### *Steering double boats*

Boats . . . boats . . . boats . . . they'll back in the news again!

Some there are a bunch of vehicles in the field with non-steering (double) boats and no replacements. What to do—what to do?

There's a change-over going on right now. A larger boat is in the works that has a modifiable upper instead of one that is fixed in—should be for better. But it's slow going through. Meanwhile of supply parties with no replacements and lots of fellows wondering what to do about their needs.

According to the latest report, the maintenance people say it's OK to go ahead and drive your truck without a boat if you haven't any spares. But have trouble get cleaned out, so try to keep 'em clean and oiled till the boats come.

Double replacements by all means, but in the meantime, don't put your truck under stress. Drive it!

With or without a boat.

### *Wipe your spacers*

If you'll peek behind the seat on your 45-46-47-2 pickup, you will probably find rust in an open space you never knew was there. It's happening along the open ends of the c/s and over back-lets too. Cleaning it up is one thing—keeping it rust-free is another. Here's what you do.

After you give the seat a good rub,

down with sand wood, wash it off and dry it thoroughly, spray the open grain with Compound, Blue Permeable Film (M&E Number 142L-307-05) (Open Number A22047), let it dry for about 48 hours. After it's good and dry, fill the open space with Sealer, Synthetic Rubber (Duck Brand - 700-62870). And that's it.

### *Go easy on this part*

I really hate to mention this—you'd think anyone who's been around airplanes

at all would know that it takes a little patience and a lot of careful reading to assemble a battery-terminal clamp and a battery-terminal post on post assembly thoroughly—especially if there's a lot of corrosion around the judging, from the number of 404 and 405A batteries showing up lately with their terminal posts snapped off back at the battery stores, a lot of people don't know that the terminal post and the battery assembly form a most difficult union.

So if you're guilty of string-arming

*If they're there  
—are 'em!*

There's been a lot of loose talk going around lately about you get a diagnosis, this and you guess diagnosis. That in your make and type just for somebody might say is the wrong way and do some up damage. Haven't you, isn't that just as silly as saying you shouldn't give the soldier ammunition because they might shoot themselves?

Those judges and things that's was all put there for a purpose and it's up to everyone who has any dealings with them soldiers—exactly what they're all for and how and when to use 'em.

Take 'em anyway, the winds.  
Probably never in your life will

you ever want a more finished. The things it can do, besides, if any one manufacturing firm's in with out knowing all the time you would give the fighter a serious headache. But their injuries suggest it's coming winter?

What you do is have all it's circles—know all the angles, that that give for just about any situation you can name—holes, points, starting value, energy, factors, even head-edges—they can all do their share of leaving things up if they aren't handled right. From all these were meant for movement.

Just figure, if they're there can 'em—but here is our 'em right!

the terminal clamp when you take it off the post—please, you make Connie very unhappy. Try the following suggestion on the job and you'll find that the post will remain on the battery as it should.

Clean off the water-pourer compartment from the terminal - clamp and post—remove the clamp bolt with a wrench and if the clamp stays closed tight, run in just open carefully with screw-driver - pointer end, you know you don't have much working room. Now take a firm grip on the clamp and lift end of bolt. You'll come up with the clamp and the battery'll keep its post.

### **MP's special alarm - pins**

This is mighty important, so let's have your good ear. Check the watch alarm pins you're carrying around for that MP, the one and the other, MP, Big or have a magnet for yourself, and if you can pick up the pins without magnet — **THROW 'EM AWAY THE FIRST** You see me then. They are good for salvage only, not the MP on you. They're not showing when they should, and I sure don't have to tell you what that means to your vehicle and/or your neck.

When you do this immediately, it'll **SHAW** new ones. H.T. . . make sure you get new pins for the same thing, you'll be using the same make machine **PERD** Q742-750000 for the above pins, and with that work number you may or may not get the new-line pins. The new-line pins are identical. Repeat what I said. The pins you should discard are whatever is on the place work.

You may be able to distinguish between the two types and hold by the difference in weight or appearance—but I'd use the magnet test and be fully certain.

Just remember, no matter whether you've had the pins going around or you have none from such, use them all. If the magnet picks up the pin—throw it away. When the pin won't cling to the magnet, it's worthless. And that's the only kind you want.

### **SAVING**

Wepdown from Army Field Forces that is the latest spirit first, take and which will be MP for all special vehicles.

The special equipment will also be standard for all new conventional type vehicles purchased for all installations will pool the money off of their vehicle used in the immediate vicinity and pool on to savings or guarantee full up of all available spirit.

EQUIPMENT... *Take care of it*

## CRANKCASE- VENTILATOR VALVE

The crankcase ventilator valve, a component found on most '74 1/2 model engines, is no bigger around than regular floor drains and a couple of inches across, and barely as long. In fact, the crankcase ventilator valve often isn't found at all, and is neglected more than other parts.

The manually controlled valves like on the MM breather system were described on Page 96, PMA, and you learned about the harm that could come to the engine if you forget to open them after under-water operation. (A similar, hand-controlled valve is used on the MM 12, too.)

An unventilated crankcase or oil-drip chamber will also suffer from sludging and corrosion when the ventilating valve isn't working for any reason, and the valve doesn't have manual controls of any kind.

This little ventilator valve's job is to scavenge the carbon and sludge-forming vapors from the crankcase. The valve is spring-loaded, and closes when the engine is idling because the manifold vac-

uum is high. When the engine speed is increased, the manifold vacuum is lowered, the valve opens and lets clean air be drawn from the atmosphere into (through the engine airfilter) pipe and crankcase, and then through the ventilator valve and valve) to ventilate the crankcase.

Because it picks up rock and slugs (and is doing its work) you've got to clean it to keep it opening and closing—otherwise it will stick out and so will the engine. For instance, if the valve falls in one groove, the engine will act like it had a heavy valve-cam-follower, and may have you scratching to try and find the trouble.

Remove the ventilator valve from the engine and hold it snug in a vice to remove the top. Clean the valve and valve seat with solvent, make sure the spring operates freely, and reassemble the valve. Check and clean all connecting tubes or lines. Do this little job every 10,000 miles — or more often, when vehicles are operated a lot at low speeds or at low engine temperatures.

# MORE GOOD STUFF ON THE M38 1½-TON

The M38 which is great when you have something like a snapping lightbulb, can sometimes behave like a spoiled baby. You know little expenses that annoy, and make you forget what money could do about using some words, mostly from editors. Just straight up down to your problem, try to simplify all those words, and maybe you'll find your answer.

## OIL LINE SLACK

If you're afraid of holding your oil line with the JLY (most suggestions of lowering the oil lines are used to stop the line from flopping against the manifold, here's a couple of more ideas. For one you can take the slack out of the line by bolting the clip attached to the timing gear cover. When the timing gear of the clip loses the center of the timing gear, you've got what you want. In fact, vehicles now in production are rigged this way. Another idea is to pull the line up through the bracket right and then wind a few

rounds of tape to hold it. You'll like this one only if you aren't against tape as an interior decoration. Try them for size.

## SLIP JOINT PROBLEMS

There are a few on the front and rear propeller shafts on the old M38 Jeeps are supposed to point out where the splined slip joints are lined up. Sometimes these arrows aren't showing at each other and sometimes they aren't there at all. When these joints aren't properly mated, it causes a whipping vibration of the shaft that damages the universal joints. To see things straight, check these arrows and if

They're mixing, mark the spots before disassembling the unit and then seal them on. The new W-D's need no screws because they have a black spline bearing only one way to match these parts in place and that's the right way.

#### WELD BRACKET SUPPORT

When you see some jockey with his head dragging, it's probably because the auto-headless support of his tail gas broke loose. You can save him this shame. The support is mounted only on the top and when breaks loose, especially on the right side where the span air hangs and balances. To keep a right head, all you gotta do is put some spot welds down the sides of the support, slowly hanging the tail right to the plate.

#### STEERING GEAR LUBRICANT

When you opened the steering gear housing you found the lubricant was a different color and consistency than that

called for in W-D's. It's usual around and around that the staff the factory work at the water-pool cavity while the lubricator take heat. This water-pool kind is checked for special purposes only, so see what's in the book and feel safe. When you need more grease in the bearing, it's better to remove the factory tube than to mix the two because these tubes seal in separate if packed in the same work.

#### TRAPING PAGING NOTE

When water traps into your carburetor through your windshield wiper when you're turning, or air into your gas filter through your primer pump-handle,

brakes, your rear air lines. You might keep the parking man right on both these springs if you want to tie up the opposite bank.

### RADIUS STOP SCREWS

Should your vehicle roll to front wheels against the hold-down brackets when you're making hard turns, it can be an unsafe proposition.

First check your wheel alignment. The fault may be there. If that's OK, then it's probably your casting radius suspension that need adjusting. The suspension for behind both sides of the front axle must be adjusted and a little extra way do the trick. The Tilt-alls for a maximum steering radius of 30 ft. For the right and 24 ft. for the left wheels of the vehicle.

If your turning angle is over at 27° from straight ahead to maximum turn, you'll find a later production model, you should be safe.

### DOES YOUR CRANKCASE GET DELUGED?

A short burst of raw gas from your

primer to start your M/M on cold mornings? Unless you happen to have your choke instead of your raw gas jet to help it start, this, but probably will give your engine a pretty bad temper. Each compression can damage your engine and because of excessive crankcase dilution and might even get it headed for Engine Room street. In addition, to keep your raw M/M engine from the junkyard and your choke in fully serviceable condition, lay off the primer except for the emergency purposes it's meant for.

The choke gadget is intended for use in soft-start weather (open, soft-start weather) when the choke doesn't hold the cylinders a rich enough mixture because the motor doesn't run over fast enough.

Another thing that'll end up in crankcase dilution is improper timing of the primer check valve, which allows raw gas to be drawn into the engine. Ordinarily if the valve is timed correctly when raw it should continue to carry air for the life of the vehicle. But just like a get started timing and things begin to happen. Slight leakage at the check valve may scarcely be noticed. Probably the first thing you know you'll be seeing an awful lot of gas. A badly timing check valve will make the engine act like the carburetor check valve was partially closed.

To check the valve, disconnect the line from the primer to the manifold at the primer and with just enough pressure in the fuel tank to keep the gas up into the primer, take it back and see for yourself whether or not there is any gas leaking through the primer.

## REVISED SHOCK ASSEMBLY

Dear Editor,

I've found that we're able to get a few more months service out of shock absorber links by loosening the tapered shafts and giving them a 1/4 turn so we put new wearing surface on the pin in the up and down motion.

The system works good on about 75% of all shock absorber links on GMC, Buick and the Dodge 1/2 and 1/4-ton vehicles.

Sgt W. B. Anderson  
Service Co 2d A/C Regt  
1st Air Div New York, N. Y.

## BUMPER LUGS

Dear Editor,

During our several months of recovery operations at Korea, we have found that many of the jobs have involved towing tanks practically buried in the mud. Now, even though we have applied every mechanical device available, the impact on the line has pulled the bumper lugs out of their sockets, sometimes caus-

ing damage to other mechanical features of the vehicles. The new idea was to cut holes through the bumper and then insert special bumper lugs that could be jammed through the holes and bolted directly to the side rail of the frame. In this way the pull comes on the stronger part of the frame.

Sgt W. Leroy Ingram  
1st Co Cavalry Recovery Company

## WET-WOOL HONE

Dear Editor,

When the wet wool distributor caps are made for use again in another Fleet's car instead of putting the caps back into service.

You'll need some cotton, a small ball of wool wool and a small sheet from an eight-inch piece of 1/2" or 1/4" webbing and with small prongs at one end made with a hacksaw. (A short straight piece of webbing and with prongs at one end attached to an electric drill, however, works much better.)

First clean the distributor cap on the outside with acetone. Rub on this dry material or brush the drying with air. Make sure there are no cracks in the body and also that there are no carbon tracks between points.

Then place the ball of wood wool in the distributor, work down the prongs of the track and in the wood wool and wipe it to remove the corrosion inside the distributor with Newt (See Fig.).

SFC R. H. Austin,

POWERSHOP AND AUSTIN, INC.,  
1001 15th Street, S.W., Wash., D.C.

### USE FINE GMC BRACK

Dear Editor:

Mechanics that have difficulty adjusting brakes on the *Shover*, get due to French adjusting screws in and corners of wheel chutches and axial pins and washer assemblies, should remember an lubricate and fix-up these items during a tune up assembly service. A little oil here will go a long way and save time.

Sgt. Stanley A. Hineson,

Service Co. 1st & 1/2 Cav. (AMTB)  
c/o 4th New York, N. Y.

(Ed. Note—That's OK, right, Sergeant.)

### 2 1/2-TON DUMP TRAILER

Dear Editor:

Here's a fix we used on the GMC, 2 1/2-ton, flat cargo dump trucks equipped with Anthony Hines. These trucks had been giving us a lot of trouble with the work blowing out the oil from coming out) in the dump body (two-cylinder). There are some mechanics at Stone Ordnance Depot claim through with an idea that not only prevents the standard equipment seal from coming out, but also keeps the piston shaft down, in this way, making the original equipment seal last longer. The machine shop at the Stone Ordnance Depot developed the idea and it worked out very successfully. Here's how you do it:

Make a sleeve to go over the end of the two-cylinder with a plate on the back end of the sleeve to create the movement or blowing out of the original seal. The small member seal on the forward end of the sleeve fits and is to be installed in the opposite direction to the original seal. Remove the sleeve to

the lens cylinder with six diametrically opposed silver screws as shown in attached photograph.

Ferris L. Gilman, OCF  
Sioux Falls, S. Dak.

(Ed Note—The jewel of the jewelry is in the words, we always say.)

#### POD WINCH

Dear Editor,

Our first shipment of model F-100 Ford MX2 Diamond T's just arrived and already we get trouble.

Our biggest headache is the winch and believe me they are really tricky. Watch that back pin when you are using the winch from the cab of your vehicle and be sure it isn't in its locked position.

And that dog or handle chain, the best watch on your sight is which is

supposed to be stored. You'll have no push that lever past the notch and as far as you can go in the right to reach that position.

Now we finally got to the operating lever. We advise putting a hinge that goes the other way and make positive sure it's in neutral. If you notice there isn't a thing to keep you from hooking this lever in gear.

Alvin E. B. Wade  
Camp Atterbury, Indiana

#### MUCKBARK

Dear Editor,

There is known the mud will build up between the wheels on a bad road when operating at a slow speed, in this way we clearing out's traction. To overcome this I have when a discarded wire cable and use it around both sets of drums, changing the ends regularly. The splices must be smooth and the loop tight enough so it won't slide the sidewalls of the tires, but not so tight as to cut the wheels or interfere with changing them. The attached diagram will show what I mean.

Pat Wayne E. Glover  
Los Angeles, Cal.

## POP THE-GATE LOCK

Dear Editor,

Failure of the locking device on the Martin dump body will give us the 440 from International Harvester dump gave us more trouble on this matter until Ed Roberts R. Jones, Jr. and Sgt. Louis Friedman of 54th Engineer Group let get their hands on me and welded together to make up a field fix that does the job.

As shown in the drawings, they made a 1/2" dia. pin of 1/2" welding rod, and supported it by two 1/2" inch wrap bands, one welded to the gate tank. Turning the pin locks the gate. They put loop-weld on the pin after it was assembled into the band so it can't fall out.

J. R. Stovis, OCT  
R. Leonard Ward, MA.

## RETRACTING-SPRING SETUP

Dear Editor,

When you need a retracting spring (which pulls inward) and all you get are compression springs (which push outward), what do you do?

Just pick a compression spring of the

right length and size, run pieces of stiff wire, like salvage chain cable or welding rods, and the rest is easy.

Draw the two pieces of wire as in (Fig. 1) and insert them in the compression spring as in (Fig. 2). There you go! The loops in the wire holding one at both ends of the spring may now be used for linkage.

An added feature of this compression is that the linkage wire separates if the spring breaks. The coils of the spring will be held by the bands at the ends of the bent wire.

Sgt. R. H. Foster  
RMC TSP ORD FORD BDN APO, IND.

## BRACK-PICK TOOL

Dear Editor,

There's more to a crowbar! Sgt. W. B. Burrows has the idea for removing the vent plug from GAC motor cylinders to check the field level, but I've found the open-end of the log wrench handles plug perfectly. All trucks have one of these wrenches.

Pat. Wayne E. Glover  
RMC OF MC  
San Francisco, Cal.

Here's A How-To-Do On Your How

5-TON  
6X6'S

MADELY — THE NEW DUMP  
AND MAY CARRY MORE

#### ENGINE OIL DIPSTICK

Maybe you've already puzzled over the fact that the oil dipstick reads like the weather: it dips when you have slanted well it can't be. The dipstick itself itself. It's a bit shorter than it could be, and won't reach all of the oil's a inch lower than 4 quarts low. However — don't let this news go to your head.

It's true that with a 22 quart capacity the dipstick level ought to be around 10 quarts low...but since you're about a cupful full, you can't go assuming there's still enough oil in the crankcase even when the dipstick shows some wet dry. And which you shouldn't have to keep operating at 4 quarts low and a dry mark, you can't go assuming around in the dark either.

"What you *would* do is hold about 1 1/2"

more on the end of the stick to make it longer, and then calibrate your wet stick at an oil change. Mark the longer stick at the level of oil after you've added the first 12 quarts. That mark will be the level of 10 quarts low-and-dry. Then add the rest of the oil, a quart at a time, and keep marking the stick. After this, there'll be no more guess-work.

#### TRANSMISSION OIL LEVEL

In case you don't already know it—the transmission oil has been reduced by 4 pints. It's now 48 pints without power take-off, and 44 pints with power take-off.

This was a necessary change because oil was dripping along the input shaft from the clutch bearing when the truck

was off level. Like when it rolled down a hill, you'd lose a pint or so of oil from the sump. Oil in the sump housing, of course, means an interference fit it's with good reason that you'll want to watch the transmission oil level.

How can you watch the new level through the old fill-hole? Easy, you tap a hole by inspection, and you are right. Naught else to do but make a new inspection hole.

Use a 1/4" drill for the hole, drill about 2" past the center of the fill hole toward rear, and 1/2" up from the center of the drain hole. Thread it with a 1/4" F. N. T. E. tap, and seal it with a 1/2" Square Head Pipe Plug (1400-00000)(Fig. 1).

After you've got the new hole, and done inspection, drain and flush the transmission to wash out the chips and sludge of metal that fell down inside.

#### OIL-GLAZE REMOVAL

Be on the lookout for a change in the position of the oil-pipe reading-rod — the manufacturer's man will be turning

around and changing the meter from their horizontal position to a vertical position. They don't last as long lying on their sides as they will standing upright. Position in life is everything.

The change is made by adding an elbow and a nipple to the present set-up (Fig. 2). Keep a check on your car so that it gets caught soon.

#### BREASING ACTION

Here about it, when the operator's finished oil and the engine keeps on firing the fuel head off — not in good order, but popping and coughing all over the place! It's called breasing action. And if it weren't for the designers on tanks, they'd run up the same way.

You've got a big engine, here. The cylinder walls are less thicker, the cylinder heavier than you'd find on lighter tanks. The thicker the metal, the more heat it holds and the cooling system doesn't always get a chance to carry it off before you turn that switch. If you've been driving hard and all of a sudden shut her off, there's enough heat left to ignite the gas, and there you are, dead.

ing action.

Let the engine idle for a few minutes after a rough haul, before you shut it off. This "bleeding" action is not just being, it'll be being with the pliers in any which position, and that's not good as you know. In idle a while, before you switch the switch.

### CUSTOM-BUILT SPRING

A lot of these 5-ton are running around with the shock-absorbent spring doubled on the tool-box bracket. That's bad. The bracket isn't strong enough to withstand the pull and it's bending like wild pain—what happens in the spring action in this case, shouldn't. And what happens when the bracket breaks, is that you'll be reaching down and pulling up the clutch pedal with your own hands while you stare with your third.

Break the spring in a hole in the frame or frame cross-member (Fig. 11 insert) or on the tool-box bracket. The frame can take it and the spring action will be good.

### UNDESIRABLE INTERFERENCE

How are your fan blades getting

along with their shroud? If you've been driving over ground that treats the chassis like a ball-bat—then the fan-mesh-and-chassis noise up and makes an awful racket.

The fan shroud isn't circular like the path the fan makes. The shroud has one of the leading edges (Fig. 12) and when the tracks change you instead of over the place, the shroud goes with it and the

fan blades make no the noise.

Now, instead of trying to stop this racket by working on the fan and trying to keep-up the fan's balance—work on the shroud. Pull-out those fan sides and give the fan more room.

### ENGINE MOUNTS

When you've got to remove the engine on the M1 and M1A, remove just the engine. Leave the rear mounting-plate where it is. Take the rear mounting-plate and bolts out of the engine—see that. Leave the plate (Fig. 13).

When the plate and rubber blocks get along along with the engine, the wiring harness gets pinched against the upper flange of the frame side-rail. This

is at the point where the wiring harness crosses the frame on its way to the instrument panel.

And another something to look out for is the wiring on the headlights. When the headlights are mounted in their lower position—without which there's an extra length of wire allowed (enough to let the headlights go raised to the higher mounting) which loops

around in the frame, it's easy to see that this floppy wire could get snagged when the engine's hoisted out. You just have to know about it, and keep at least one eye open.

### COVERING SCREWS

It's not you who can't tighten up those governor mounting screws—it's the screws themselves that won't stay tight. A lock-washer isn't used since you can't loop a water-proof seal if you stick in a lock-washer.

They're using a new screw for the governors, it's got a block of nylon in it that'll clamp itself in the screwing operation and really lock the screw tight. In the meantime, though, you'll be in a bit

of a bind because the governor'll become loose. The screws will just have to be tightened . . . when. Which means that first you'll have to take the cover off the governor. It isn't the cover across that let the governor work loose, but the two mounting screws under the cover.

### TRANSFER-CASE SHIFT-LINES

The transfer-case shift-line clip, as on these jobs an identical right one. They'll be changed in production, and the length of each will vary enough so that switching them when they're being connected will be impossible. But on your 5400, the shifts are against you going from hooked up the way they should be.

If you're not experienced at handling this heavy work, you'll know immediately that something's wrong if the shift-lines have been switched. The case will—and you feel a noticeable drag. It's easy, though, not to be that sensitive to performance.

One way you can be sure of the right

lock-up is to check it, jack up one front wheel (the other front wheel must be on the ground). Make sure you've got air pressure—then with the main line in a forward gear, the locked wheel should run freely forward. You shouldn't be able to spin it backward. Then shift to the reverse gear. With the gear in reverse, you'll be able to move the wheel backward but not forward.

Once you know that the lines are connected right—how about making them? For a job of white paint or a new flange or something, or 500 or so of line.

### EMERGENCY BRAKE

These lines have emergency brakes that only use emergency brakes. They are so good that forgetting to adjust the emergency brake while out on the highway isn't just a bad idea—it's a disaster. It has happened.

Emergency brakes actually have a shoe that straddles the brake drum and presses it all the way around. But these brakes work with one shoe shoe—one outside the drum, one inside the

drum (Fig. 7). And what happens is that so much heat is built up in this one section that it fuses the metal.

You can do damage at good a job of demolition by riding with the emergency brake on, or anything your TM could give you no destruction of material. Only in this case, you are your own enemy.

### WINDSHIELD WIPERS

If you've been having trouble with the windshield wipers going on or off, check the mounting screws. You'll probably find that one of them is blocking the wiper's passage. When you find the screw, drop it in and. You'll have active wipers from then on even when it isn't gonna rain or snow.

### BATTERY TROUBLE

What you need to keep that battery on the M1—the dump truck—from getting a constant shower of rocks and dirt and debris, is a higher pressure plate on the gas tank. Not only will it keep the battery out of trouble, but it'll also keep the gas tank clean and unobstructed.

(Continued on page 229)

Easy Does It On

## PLASTIC LAMP-LENS

What every young man should know about plastic lens—headlight, blackout light, map light, etc.—is that while they may look and feel like glass, and substitute for glass, they can't be treated like glass.

You'll find plastic lens on all war-torned vehicles with the 18-volt electrical systems. And if the plastic isn't handled with a kid and a prayer, you'll find no lens at all on these vehicles.

Blinded plastic has a surface reaction—something that attacks the surface, replaces the texture and causes what is known as "cracking" or "blacking". It could get worse — the plastic softens, warps, and begins to melt. None of this is good.

There are a number of plastic cleaners on the market, but not all of them are good for the particular type of plastic in your lens. These cleaners aren't readily available to you anyway—especially not right when that beautiful camouflage job of mud has to come off. Toss hot, hot in soap and water, or just plain water, applied gently with the bare hand.

Any vigorous rubbing with a cloth builds up an electrostatic charge on the plastic so that it attracts dust particles from the air. Grinding the dust around the lens will scratch it all to hell. A damn chance would release this charge,

but he might save the chance a clean, clean, clean.

SB 7-4 (28 July 1944) in preparation of Ordnance material for shipment says: Paint head lamp lenses on all vehicles with black gasoline-soluble lacquer camouflage paint (powder form) . . .

As old habits, what goes with glass doesn't go with plastic. Before painting lenses, you'd sit well to place a piece of brown paper or some other non-adhesive material between the lens and adhesive, and paint over the adhesive. If either paint or adhesive gets on these lenses, you're going to be driving blindfold without meaning to.

The secret of keeping plastic lens crystal clear and glass-like is in knowing what will attack the plastic and what won't. Here's a check list.

<u>Subst.</u>	<u>Washing/try!</u>
Soap & Water	Masking tapes and lacquer tapes
Water & Soap	Enamel, dry cleaning, acetone, benzene, carbon tetrachloride
Water & Soap	Fluoresc. paint & lacquer
Soap & Water	Enamel & oil & grease
Water & Soap	Ironing & steam-dressing irons/presses
Soap & Water	Paint

#### HARVEST BATTERY POLARITY

Dear Half-Mast,

In my mind we have a number of B.B. auto motorcycles that are used quite a bit. Right along we've been installing the last, never positive ground on all of the cycles until suddenly we noticed the points on the voltage regulator were burning out one week of the cycle. When the TD didn't come up with the answer we started wondering about the polarity of the current. Then an assistant's cousin B.B. motorcycle dealer, who notified us that the battery should be installed negative ground.

In what we did was completely double the battery rules and change them rules and they then we haven't had any trouble. Now what would you have done? Did we do the right thing?

Cpl. A. E. V.

Dear Cpl. A. E. V.,

What you did was all right but you didn't really have to change the battery. Simply discharge it completely (turn on

all the lights and leave 'em on until the battery's all used up). Then recharge it in the original direction and reconnect it with negative ground polarity. And here's something to keep in mind. It isn't wise to charge any motorcycle battery at a rate of more than 3-4 amperes an hour. Any more than that—and your battery may be a gone goner!

*Half-Mast*

#### TANK TRACK REPAIR

Dear Half-Mast,

Can you advise us up on this problem?

If the sprocket is jammed with splintering like built up on an M4 or similar type track, and the track is still loose, is it advisable to remove one link? If a link is removed from one track, and the other is tight enough not to increase rubbing on a link, will this condition have any ill effects on driving? One track will have slightly more surface touching the ground.

Sgt. F. L. M.

Dear Sgt. F. I. M.,

When the crack it will see how about the air-compressor, all you can do is pull out a block. One block's difference between the tracks won't affect the running.

*Half-Track*

#### MINI COMPRESSOR

Dear Half-Track,

Example of an idiot over-arguing about maintenance on the air-compressor air-chamber on the M1000 tank. How did you know that the dove which causes the engine air-chamber and the air-compressor air-chamber takes care of feeding clean air to the air-compressor and no maintenance is needed. Forget Wile's right!

A. M. P. OCT 4

Dear Mr. P.,

If that was a money bet, pick up the chips. That last you speak of is only for starting and when the engine is started it is removed as when in the main air-chamber, you're going to let this into the compressor, eventually from the oil system and back . . . now no M1000 tank to handle and clean that air before it hits the compressor.

*Half-Track*

\*Delicious Corps Technician

#### FOR BRABE FEED!

Dear Half-Track,

While driving one of the new M1000 utility trucks and long ago I came across a slightly safety hazard which on my mind could be easily, quickly and cheaply remedied. It prevents the brake

pedal operation approximately 7" or 8" and it is located that when a man steps his foot straight on the right or the left side of the brake pedal, happens to be to step suddenly—what happens? His foot is pulled down by the brake pedal because the shoe is caught on the downward lip. Really accident!

Let's not discuss an above safety hazard all we can. Here are a couple of suggestions. Why not move the pedal to the left and remove its lip? Or remove the lip and round off the corner?

Sgt. W. E. N.

Dear Sgt. W. E. N.,

We'll go along with you about removing the downward lip on the pedal pad and rounding off the corner, or you might even take the accelerator foot out because it to give your foot a little more room.

Now as to moving the brake pedal, that would be a good idea if there were enough space. But the pedal is mounted on the inside of the left frame rail. The master cylinder is mounted inside the frame rail and directly behind the brake pedal. The brake pedal cannot be moved to the left because it must align with the master cylinder and there isn't space to move the master cylinder to the left.

*Half-Track*

## PAINTING BATTERIES

Dear Mr. Man:

If your mechanic find it hard to keep corrosion off battery posts and terminals, let them try this. Remove the battery, clean with water and wire brush, then dry with air gun and then paint posts and terminals good white GEL paint. Re-plate the terminals on the post and after the paint dries there won't do any corrosion for about six months. Best of all, you won't get slipped when he figures pay you a visit. This is much cheaper than every year.

Mr. W. L. D.

Dear Mr. B.,

Now, Mr. B.—wouldn't paint a battery under any condition. If you want to get inside with a paintbrush, dip it in cup grease or petroleum . . . but paint? Not this fellow.

If you wash off the corrosion with plenty of water, take the battery apart and cable terminals with a light file of petroleum or grease job maintenance is not goodly, replace the cable terminals and keep the battery clean, should be no more corrosion, ever. If you will get corrosion, you get a short positive electrical system.

Like with everything else that's made by the beauty folks—ever wish a girl make up her face? If take care and protection—and most of all make her get your happy with a brush. Then she's beautiful, why when you need your vehicle more so that it won't go . . . and you'll never suspect a hair of paint plugging the battery will ever fade . . . so a thin layer of insulation that won't be the current through.

Now, Mr. B.—can vehicles, with shiny's better than glassed!

*Self-Start*

## ALL BRASS-WHEEL BEARINGS

Dear Mr. Man:

Read a statement, in the June issue, that you should put an extra pound of grease in the rear wheel hub cavity on the WV.

Tell me, Mr. Crystal Ball, what grade is grease do?

Cpl T. E. B.

Dear Cpl T. E. B.,

Grease contains oil. If your rear wheel bearings start to get a little hot, because they don't have enough lube, more oil is going to seep from the rear reservoir of grease in the hub cavity and cool them before they get too hot and seize up the works.

*Self-Start*

## NEW PUBLICATIONS

Dear Mr. Man:

We have a new *MM* (?) and *Self-Start* International Stamp Book, and coming in the *Measurement Manual* as an *MM*. How can any of each be obtained?

Mr. R. E. B.

Dear Mr. R. E. B.,

You're out of luck on an *MM*, for the *MM* is this time. That issue's been published yet. The *MM* you want is *MM* and *Self-Start* publication is waiting for your request.

*Self-Start*

## NO MORE OVERHEATING

Dear Half-Mast,

We have two *MCY* tanks in our *Boyer* *Plymouth*. One of these tanks runs as hot as the other but it never runs miles without it boiling over. We just saw engines that never do this. We're total everything in the tank and we're crank long, got any ideas?

Cpl. R. F. Z.

Dear Cpl. R. F. Z.,

Yeah, I got ideas—but they're started, as both as business. When you get out the pump in the tank, there's two things to consider 1—Are all the features that contribute to cooling on the burner? 2—Is the hot engine doing all the work, consequently overheating?

In addition to your regular cooling check, check the water in the radiator cap and in good condition, check the belt for adjustment (just as pulleys may have given false adjustment); make sure ballhead plates and transfer case cover have not been removed (allows for air recirculation); synchronization of engine synchronization of hydraulic transmission, hot-air intake.

Watch for the galvanic plating inside hot water pipes, cooling, and clogging filter fuel pumps in tanks sometimes become coated with varnish caused from water gas, or may be gassing the pump.

*Half-Mast*

## ALL-FLANGE-UP TEAM

Dear Half-Mast,

Talk it for what it's worth, but I've been able to stop sweating about over-

heat these tanks on my burner job by substituting *Permatex* #2 for the seal-flange gaskets. I applied the *Permatex* #2 to the solid metal-to-metal contact of the seal-flange and deck and then inserted the flange bolts the same as usual. Did this a month ago, and there's been no sign of leaks (leakage, or loose bolts).

Cpl. G. W. S.

Dear Cpl. G. W. S.,

Well, I'm thinking that if you keep your flange bolts properly tight to begin with, shouldn't be any need for sealant either—and I don't go along with *Permatex* #2. It's heavy stuff—was the glue. Use one coat and you'll never get your tanks off, and you think and it serves no purpose at all... and to get it just right in a place like this, is a real neat trick. As long as *Permatex* won't keep your bolts from loosening, because vibration will stretch 'em. And until you can tighten the bolts, the gasket'll take care of the expansion—something *Permatex* won't do.

With us the gaskets (with some *Permatex* if you like), keep these bolts tight and your job will thank you by holding the oil and keeping her out from leaks.

*Half-Mast*

FIVE NEW WAYS TO  
GET AWAY FROM TOWS

## M34

### M34 THROTTLE STOP SCREW

Heard a story the other day about a pack mule who was carrying a load along a river bank. He thought he was hauling sugar and deliberately slipped off the bank and into the water. His idea was that the sugar would dissolve and lighten his load. Poor mule had sponges in his pack.

Heard another story that goes like this:

"When your M34 hits the 1000-mile mark, it's time to get rid of the throttle stop in your governor. When you remove this **part** and throw it away, make sure you replace this **part**."

This bit is a part of your governor and carburetor assembly. It holds the governor right against the carburetor, making the **bit** leak-proof. If the **bit** isn't leak-proof and you and your M34 takes off like a submarine in the low stream you come to, what happens? You sink half the stream into your brake manifold and you're on the bottom like a sack of sponges.

Think there's got that screw right back on you're gonna be taking that poor mule on your back.

### M34 TOWING AND BOLL BACK

"The device known as 'over-center dog-gie' is a disabled vehicle that was designed in the first place," is a personal favorite of maintenance shop engineers. "We'd save time and partly closing the doors and getting 'em up ourselves."

If the truck can be towed with all wheels on the ground, you damage no axles, wheels, or axles; shift into neutral position and transfer the transmission into neutral position, but the gear in the transfer case revolving and will cause enough lubricant splash for the bearings.

If the transfer is damaged, disconnect drive shaft's at Forward Range and Forward-over-center Range and remove shaft's to frame.

Whenever the truck is to be towed with front wheels off the ground, front

Of itself should only be tilted enough to clear ground on all four wheels on both sides and across the roadway. Otherwise the propeller shafts at the forward (Fig. 108), become the end of the shafts on the frame.

Treads should be covered backward only when all other methods have proven impractical. To use such a tire over a hole off the ground, depresses the propeller shaft at the forward flange and sends the end of the shaft to the frame.

And here let it be known that rolling the track backward for any reason, regardless of the transmission lever being moved in frame face movement backward even though the result's cause is in nature, providing it is equipped with the double-spring overrunning clutch. Of course a neutral or any forward speed transmission position is OK for forward movement, or starting. (There is no free backward movement possible with the single-spring clutch until the propeller shaft is removed).

**NOTE:** Before removing prop shafts, always take one wheel on the front side and one wheel on each rear side clear of the ground to relieve torsional strain (wind up) and avoid heated handles.

### HOOD-HOLD-BACK BOB

Mounted on the cork, in front of the driver, is a red, heavy leather or a tough, hold-back mat.

When some of us big guys need a bit of extra support around in the engine compartment we just lift the hood off the hood supports and placed it front end of hood's end stops it back against the windshield. Strong comes a gust of

wind, or a helping hand, and when gone the hood. It's not classy about what it means—short, forgets or somebody's big fat clothes.

We pick ourselves up off the ground and start to grumble about why they didn't fix a way to hold that hood back when you've got it raised all the way.

Wind-hold-back mat on the cork in front of the windshield! Now ya tell me . . . now ya tell me.

### TRANSMISSION OIL LEVEL

Get's been getting into the clutch bearing—on clutch. Why? Because some fellas don't have too much oil goes into the transmission and overheat it. When you overheat the transmission the oil slips down from the clutch bearing, you see the clutch drives shaft bearings, and break up the clutch.

When filling your transmission, keep a finger in the filler-hole between gears. When the oil comes to about 1/2" below the hole—that's enough. **CHECK THEM AGAIN WHEN THE OIL'S WARM.** If don't understand, bring the oil to the correct level by draining.

### WATER IN GAS TANK

Condensation or leakage is going give you an accumulation of water in your gas tank. It'll settle around the copper filter filter in the bottom of the tank.

To get rid of this water, you first wipe off the dirt around the filter opening and cap and remove the fuel tank filter cap. If you don't know how much gas is in your tank, and, in case something should go wrong, you'd better have a couple of spare containers ready—enough to hold 10 gallons. Next, remove the filter pump plug at the base of the tank and fit the water drain out—only take a second or two. For the pump plug, both good's tight. Connect the necessary air line as direct one of the two necessary air line fittings. (Located in each side of side on

dash panel) and hook the air line to the gas line in back of the fuel pump. Be sure to do your blowing IN BACK OF THE FUEL PUMP. If you blow through the fuel pump, pressure's going to rupture the diaphragm.

When you're blowing out the line be sure the gas tank cap is off. If it's not, you're going to build up pressure in the gas tank and something's going to let loose.

There may have been some moisture or water in the line that was pushed through into the gas tank during the blow job. You won't go wrong if you have off the gas tank cap, take out the pump plug and drain her again. For the pump plug back in good's tight. Before you head her with gas.

**WHEELS, WHEELS—Open Axles**

(continued from page 20)

About 1/2" thick plate will do the trick (Fig. 12). It should be cut about 18 1/2" high and 27 1/2" wide. Have it welded onto the steel plate that's there now, so frame is between you lower foot. If you choose to weld, remember you're working right next to a gas tank—if you prefer to use bolts, place a sheet of metal behind the axle you aim to drill to stop the drill bit before it hits the tank. To hold the wide metal plate, use really solid, you can anchor it to the side of the steel tank just above the gas tank) with a nut and. In any case keep the new addition a good 1 1/2" from the dump body.

And to keep the side on your knuckles and ribs, lower round off the corners and level the edges.

## Connie Rodd's BRIEFS

### **DANGER! GASOLINE IN THE AIR CLEANER**

Can you get into the air cleaner on your 1981-1984 Buick Full-ported-tank level is the bottom. It's located just outside gasoline—and under a 400-pound sub-pressure, the gas is forced up the breather line and into the air cleaner. Naturally, it mixes with the oil and gums up the works.

If you do find gasoline in the air cleaner, there's a valve in the 1/2-inch and clean the air cleaner and replace oil to the marked level. (Change engine oil—usually gas diluted by the weather—from the cover, a bottom discharge cap and lock inside for signs of oil or gasoline—which get in through its vent pipe from the air cleaner. 4. If the gas tank is too full, drive the buggy around for a while to lower the gas level before leaving it sit in the sunny sun.

### **HEADLIGHT ADJUSTMENT**

There's been a revolution. THORNDYKE on the procedure for adjusting headlights (75 Magazine, August). Using the same method and measurements, it's now SOP to make the adjustment on vehicles without a load. The theory is that the procedure given will ground the beam at 100 feet on an empty vehicle—then when the vehicle's loaded, it'll automatic-

ally raise the beam to give stability for a greater distance, but it still won't be high enough to blind the oncoming driver.

### **STARTING THE ACE**

Time's wasting your time, right? The down on the M&M System to get a rich charge of fuel into the main field... the accelerator pump is vacuum operated and not mechanically linked with the down-b linkage. On all cool-engine and cold-engine starts, the M&M should be hand-choked to avoid unnecessarily long cranking periods.

### **WATER-PROOF SPARK PLUGS**

Changing brands isn't always a cure in the case of breakdown of water-proof spark plugs. Some plugs show no crack or imperfection to distance where maybe 1000 to 1,200 is good. As a result of this terrible experience, the insulation on the high-tension cable gets broken down by the spark—allowing the spark to ground to the base.

When you've got trouble along the ignition line that's the result of a grounded high-tension cable—replace the spark plugs as well as the cable, else the new cable will end up the same way.
